## 66 **1. Introduction**

### 67 ***Background***

68 Dietary exposure assessments are a key component of chemical risk assessments for  
69 food additives and potential food contaminants, such as pesticides or veterinary  
70 medicines; however, there can be differences in the approaches taken to these  
71 assessments in different regulatory areas and between regions internationally. There  
72 are historical reasons for this, and each area of regulation has evolved independently,  
73 based on factors such as the different regulatory contexts, the nature of the data  
74 available, or strict legislative requirements in certain areas.

75 Within the United Kingdom (UK), there are differences in the current approaches to  
76 assessments of chronic dietary exposure between the Health and Safety Executive's  
77 Chemicals Regulation Division for pesticides (HSE-CRD), the Veterinary Medicines  
78 Directorate (VMD) for residues of veterinary medicines, and the Food Standards  
79 Agency (FSA) for chemical contaminants and other chemicals in food. Furthermore,  
80 there are differences in how these assessments are conducted internationally for  
81 pesticides and veterinary medicines, and these differences may increase as  
82 methodologies change.

83 In addition, following exit from the European Union (EU), it is timely for UK regulators  
84 to consider the approaches they might wish to take in the future.

85 It was therefore agreed to review the current approaches to chronic dietary exposure  
86 assessments taken by HSE, VMD and FSA, accounting for the principles and aims of  
87 the exposure assessments, the reasons why differences in approach might  
88 legitimately be taken, the uncertainties associated with different approaches, and the  
89 uncertainties that exist with exposure assessments in general and how they might be  
90 reduced (if necessary).

91 A team of risk and exposure assessors from HSE, VMD and FSA held 10 meetings to  
92 consider this topic. The agreed terms of reference were:

- 93 • To consider approaches to chronic dietary exposure assessment, agree and  
94 set out the general principles to be followed by Government departments, and  
95 to set out a tiered system of different approaches, from simple and conservative  
96 to increasingly complex and refined, recognising that different departments may  
97 have different requirements.
- 98 • To explain the appropriate criteria for using these approaches at the different  
99 tiers and the uncertainties associated with following the different approaches.
- 100 • To capture the underlying uncertainty in food consumption and occurrence  
101 data.
- 102 • To identify potential research that would reduce uncertainties in exposure  
103 assessments.

104 The intention was to present the draft report to the Committee on Toxicity of Chemicals  
105 in Food, Consumer Products and the Environment (COT), the Expert Committee on  
106 Pesticides (ECP), and the Expert Committee on Pesticide Residues in Food (PRiF)  
107 for their input and feedback ahead of finalisation.

108 ***Principles of exposure assessment***

109 Dietary exposure assessments are an essential component of the four-stage risk  
110 assessment process of hazard identification, hazard characterisation, exposure  
111 assessment, and risk characterisation. This approach is used by [CODEX](#), international  
112 regulatory bodies, and food safety agencies, including UK Government departments.  
113 The outcomes of the first two steps of the process inform the approach required for  
114 the exposure assessment, e.g., whether chronic and/or acute dietary exposure  
115 assessments are required. The resulting exposure assessment can then be compared  
116 with a health-based guidance value (HBGV), a threshold of toxicological concern  
117 (TTC), or, alternatively, a margin of exposure could be calculated at the risk  
118 characterisation step.

119 There is general agreement that dietary exposure assessments should provide dietary  
120 exposure estimates that are conservative (i.e., highly protective of health) and be  
121 conducted using methods that are fit for purpose (WHO, 2020). They should address  
122 the general population, as well as specific population subgroups that have been  
123 identified as relevant from toxicological profiling (e.g., infants, children, pregnant  
124 women, older adults). The method(s) used should take into consideration non-average  
125 individuals, such as those who are disproportionately at risk to the adverse effects of  
126 the chemical under consideration, and those who are high consumers because they  
127 habitually or occasionally consume large portions of foods containing the chemical,  
128 consume many foods that contain low levels of the chemical, or habitually or  
129 occasionally consume foods with very high concentrations of the chemical (WHO,  
130 2020).

131 Several approaches are available for dietary exposure assessment:

- 132
- 133 • simple deterministic or point estimates, which use single values for the  
134 concentration of a chemical in food and for the level of consumption.
  - 135 • refined deterministic estimates, e.g., empirical distributions of food consumption  
136 combined with single values for the concentration of the chemical in each food,  
137 or *vice versa*.
  - 138 • probabilistic/stochastic estimates, which use parametric or non-parametric  
139 techniques to generate a distribution of exposures.

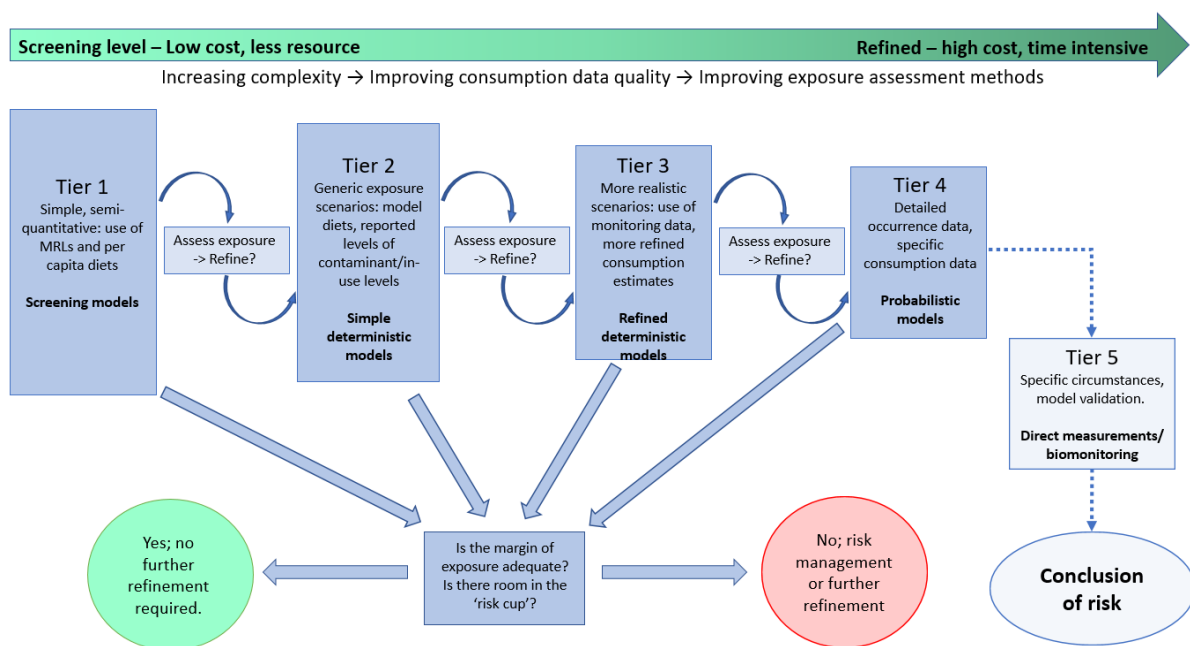

139 The ability to conduct refined, realistic estimates of dietary exposure depends on the  
140 available resources, so tiered approaches are often used in various stages of risk  
141 assessment, including exposure assessments (Ingenbleek et al., 2020). Tiering in  
142 exposure assessment means using simple, conservative approaches when resources,  
143 including time, are limited, or where further refinement of risk is not required (low tier),  
144 and more complex and precise approaches when further refinement is needed (higher  
145 tiers). Thus, a low tier is typically a data-poor situation involving conservative  
146 assumptions, whereas at higher tiers, more data are available, allowing assessments  
147 to become more accurate with reduced uncertainty, and eventually the potential to use  
148 probabilistic approaches (Ingenbleek et al., 2020).

149 Where low tier approaches are used (sometimes referred to and used as 'screening  
150 approaches'), the aim should be to overestimate the potential dietary exposure of high  
151 consumers by using conservative assumptions for food consumption and the

152 concentration of the chemical in food, in order to avoid situations in which dietary  
153 exposure is underestimated and the assessment erroneously indicates that there is  
154 no safety concern (WHO, 2020). Similarly, where more refined, higher tier, approaches  
155 are required, they should still be designed so that any potential high dietary exposure  
156 is not underestimated (WHO, 2020).

157 Taking a tiered approach means that the exposure assessment can stop, and the  
158 risk assessment concluded, without using unnecessary resources, e.g., if it can be  
159 concluded from a low tier approach that there is no significant risk to consumers.  
160 Alternatively, if a significant risk cannot be excluded from lower-tier approaches, then  
161 either risk management action may be taken at that point, or the exposure assessment  
162 may progress to higher tiers (Ingenbleek et al., 2020). See figure 1.

163 **Figure 1:** Diagram illustrating a tiered approach to dietary risk assessment

164 However, not all exposure assessments proceed through tiers; a more realistic  
165 estimate of exposure may be used in the first instance if the resources are available  
166 to do so (WHO, 2020). In many assessments of regulated products, the exposure  
167 assessments do not proceed from lower to higher tiers. Instead, the tier(s) applied are  
168 predetermined by the available data, the problem formulation, the regulatory context,  
169 and/or the legislation in place (Ingenbleek et al., 2020).

171 Exposure assessments should be clearly documented (WHO, 2020). This includes  
172 information about the dietary model and food consumption data used, the associated  
173 concentrations of the chemical in food (including the data source(s) used), the model  
174 choices, data limitations, and uncertainties.

175 Dietary exposure assessments may be population-based or consumer-based,  
176 depending on the purpose of the risk assessment. In this context, 'population' means  
177 all the respondents in a dietary survey, whereas 'consumers' means the subset of  
178 respondents who reported consuming foods containing the chemical of interest. If the  
179 chemical of interest is present in non-staple foods (i.e., those not consumed daily by  
180 most people), then a population-based exposure assessment may underestimate the

181 potential dietary exposures for regular consumers of the foods containing the chemical  
182 of interest. In this case, a consumer-based approach may be preferred, as it would  
183 lead to a more conservative estimate of high-level exposure, and thus be more  
184 protective.

185 The nature of dietary survey data may also affect whether a population or consumers-  
186 only approach is taken. For example, if data from a 24-hour survey are used to  
187 estimate chronic exposure, they are only considered reliable for estimating mean  
188 consumption for the total population, and not for identifying the number of consumers  
189 of a food, or for estimating exposures of consumers only. For dietary surveys  
190 conducted over multiple days, care is still needed in estimating long-term intakes, as  
191 short-term data can lead to underestimates of the proportion of the population who are  
192 consumers, and overestimates consumption by consumers on a long-term basis.  
193 Where dietary surveys are conducted over 2 or 3 days, a lower percentile (e.g., 90<sup>th</sup>  
194 percentile vs. 95<sup>th</sup> or 97.5<sup>th</sup> percentile) can be used to represent high-level consumers,  
195 to avoid overestimating long-term exposures. This is the approach taken by, e.g., the  
196 US Food and Drug Administration (US FDA) and Food Standards Australia New  
197 Zealand (FSANZ) (WHO, 2020).

198 Statistical approaches are also available to estimate 'usual' consumption of foods, or  
199 exposures to chemicals, from short-term dietary data. These aim to remove within-  
200 person variation, resulting in distributions of exposure which are narrower. Such  
201 models can be time and resource intensive. They are usually used on a case-by-case  
202 basis, with the input of expert statistical advice. Exposures can be estimated without  
203 using a model for 'usual' intake, provided it is explained that any high percentiles of  
204 'usual' intake are likely to overestimate the exposure on a long-term basis, to an  
205 unknown degree.

## 206 2. Description of approaches in different fields

207 Food additives, supplements, naturally occurring toxins, and other contaminants - FSA

### 208 **General overview**

209 FSA carries out dietary exposure assessments for a range of chemicals that can be  
210 found in foods and supplements, including food additives, pesticide and veterinary  
211 medicine residues, residues in animal feeds, contaminants, food contact materials,  
212 and naturally occurring toxins like mycotoxins.

213 The current FSA approach to estimating chronic exposure is to determine food  
214 consumption, multiply it by the concentration of the chemical of interest in the food,  
215 and expressing this as either a quantity per person per day, or per kg bodyweight per  
216 day (see figure 2).

### 217 **Figure 2: Dietary exposure calculations**

$$DietaryExposure = \sum (Food\ chemical\ concentration \times Food\ consumption)$$

Where: 'Food chemical concentration' is the concentration of the chemical of interest in the food and  
'Food consumption' is the amount of the food that is eaten.

$$DietaryExposure = \sum \frac{(Food\ chemical\ concentration \times Food\ Consumption)}{BW}$$

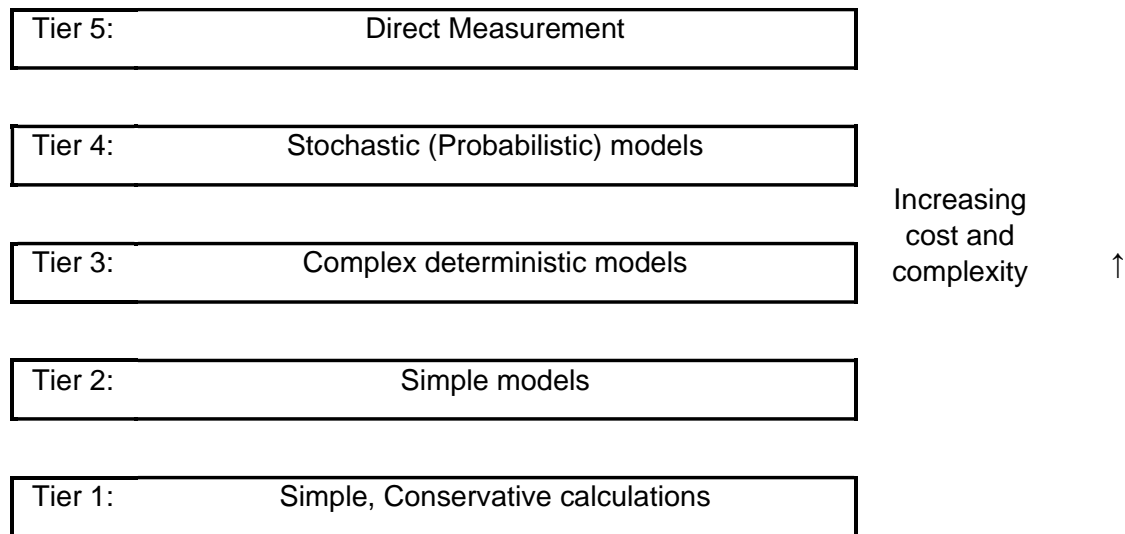

Where: 'Food chemical concentration' is the concentration of the chemical of interest in the food,  
'Food Consumption' is the amount of the food that is eaten, and BW is the body weight of the  
consumer.

218  
219 Details on how this consumption and chemical occurrence data are derived are given  
220 in the following sections.

### 221 **Tiered approach to exposure assessment**

222 Generally, FSA adopts a tiered approach to selecting the best method to carry out  
223 exposure assessment, considering factors such as sources of uncertainty, perceived  
224 risk, available time and resources, and suitability of the method. The assessment is  
225 consistent with the approach adopted by the European Food Safety Authority (EFSA).  
226 Currently, the main approach to exposure assessment has been to use deterministic  
227 and distributional methods; however, the use of more complex methodology, such as  
228 probabilistic modelling, is considered on a case-by-case basis for refining an exposure  
229 estimate. See figure 3.

230 **Figure 3:** FSA tiered approach to exposure assessment

231

232 Most FSA exposure assessments utilise Tier 1 or Tier 3 methods.

233 **Tier 1**

234 Tier 1 involves carrying out basic calculations based on conservative worst-case  
235 estimates of chemical occurrence and consumption data. These could be based on  
236 back calculations (e.g., knowing an established Acceptable Daily Intake (ADI) and the  
237 level of chemical in a food, then back calculating how much of that food would have to  
238 be eaten to reach the ADI, after taking account of background exposures). If the simple  
239 estimates are well within established safe limits, then the assessment will not proceed  
240 further. If the conservative estimate gives any cause for concern, the exposure  
241 estimates may be refined with additional information.

242 **Tier 2**

243 Tier 2 involves using mean or high-level food consumption rates taken from published  
244 summary tables of food surveys, such as the National Diet and Nutrition Survey  
245 programme (NDNS) or Diet and Nutrition Survey for Infants and Young Children  
246 (DNSIYC); see 'consumption assessment' section for more information on surveys.  
247 Calculations are carried out similarly to tier 1, but more details such as migration from  
248 food packaging, and consumption of multiple foods, will be accounted for.

249 **Tier 3**

250 For tier 3 assessments, FSA uses Creme Global software, which is statistical software  
251 that allows the estimation of dietary exposure from individual dietary survey records  
252 for different subgroups with single values of a chemical concentration in food. The  
253 program uses the 97.5<sup>th</sup> percentile consumer to represent reasonable high-level  
254 consumption. See the section on Creme Global software for more detail.

255 **Tier 4**

256 Tier 4 covers the use of probabilistic modelling. Probabilistic methods represent a  
257 higher degree of complexity, allowing consideration of the full range of chemical data  
258 and/or other parameters. The models randomly sample the full distribution of chemical

259 concentrations in individual items of food, in addition to the distribution of consumption  
260 data provided by the NDNS; these data are combined and presented as a distribution  
261 of likely exposures. Probabilistic modelling offers the possibility of more realistic  
262 estimates of exposure and useful refinements in analysis which go beyond routine risk  
263 assessment.

## 264 **Tier 5**

265 This is a direct measure of exposure for a specific critical group, using methods such  
266 as biomarkers or duplicate diet studies.

### 267 ***Consumption assessment***

268 The main source of data used by FSA for estimating dietary consumption is the NDNS.  
269 A rolling programme of the NDNS was set up in 2008 to collect data on a continuous,  
270 annual basis. The age range of participants is from 1.5 to 95 years of age and excludes  
271 pregnant/breastfeeding women and people in institutions. One of the major  
272 components of the NDNS is a detailed record of a person's diet during 4 consecutive  
273 days, via a written food diary (2008 - 2020; years 1 - 11). Up until 2020 (year 11), the  
274 NDNS used a 4-day un-weighed diary as the dietary assessment method for the rolling  
275 programme. From year 12, 'Intake 24' has been used. This was introduced in order to  
276 improve data quality and maximise value. It is a 24-hour recall method used to obtain  
277 dietary data. Participants are asked to complete 4 time-spaced recalls within 3-5  
278 weeks using an online platform, rather than the 4-day written diary entries.

279 Another main source of data for FSA is the DNSIYC. This was commissioned by the  
280 Department of Health (DH) and FSA in 2011 to provide detailed information on food  
281 consumption, nutrient intakes, and nutritional status of infants and young children aged  
282 4 - 18 months living in private households in the UK. This survey provides the only  
283 source of high-quality, nationally representative data for this age group. It was in the  
284 form of a food diary filled in by the parents of the children over 4 consecutive days.

285 The NDNS and DNSIYC allow flexibility in how critical groups might be considered;  
286 this is also supported by the Creme Global software. As mentioned previously, these  
287 data are entered into the Creme software and can be manipulated to give consumption  
288 or exposure assessments for specific food groups and (or) consumer groups. The data  
289 can be filtered according to age, gender, and socio-economic status, amongst other  
290 parameters. More detail on the Creme software is given later in this report.

291 Additionally, FSA commissioned a project for a recipe database, to help ensure that  
292 foods consumed as ingredients of other foods were accounted for in dietary exposure  
293 assessments. The initial project was carried out by the Medical Research Council's  
294 Human Nutrition Research Unit (MRC HNR) and was completed in 2015. The output  
295 was 8397 recipes with guidance notes and a project report. Recipes continue to be  
296 added each year when new data are gathered from respondents in the NDNS rolling  
297 program. This database supports the use of NDNS and DNSIYC data in consumption  
298 assessments.

299 Other surveys, like the Expenditure and Food Survey (EFS) (Family Food, 2007),  
300 provide supporting information on food consumption. This survey was carried out  
301 annually and provides data on food purchases at a household level. This is limited in  
302 its usefulness for assessing food safety, as the data provided are population averages.

303 However, as it was a continuous survey, it was useful for tracking food consumption  
304 patterns. The Expenditure and Food Survey has now been replaced by the Living  
305 Costs and Food Survey (LCF) (Living cost and food survey, 2012-2016), where food  
306 consumption is also estimated based on purchasing patterns.

307 Other methods of sourcing consumption data include using information from measured  
308 portion sizes, manufacturers' feeding instructions (e.g., for infant formulae), or  
309 recommended dosages (e.g., for dietary supplements) to show average exposure or  
310 to assess the number of portions required to achieve a certain level of intake. For  
311 rarely eaten foods for which there may be few, if any, recorded consumers in available  
312 surveys, typical portion sizes can be used. McCance and Widdowson's 'The  
313 Composition of Foods', Sixth Summary Edition, provides comprehensive nutrient data  
314 for over 1200 of the most commonly consumed foods in the UK (FSA, 2002). This is  
315 often used by FSA to estimate portion sizes or food composition for consumption  
316 assessments.

### 317 ***Occurrence data***

318 Sources of occurrence data used by FSA vary. Data may be obtained from incidents  
319 where a particular food has been found to have a chemical concentration above a  
320 certain threshold. Data from FSA surveys have also been used for assessment of  
321 dietary exposure. Data may also be from research projects on foods or chemicals of  
322 interest. Exposure assessments are also used to interrogate the results of monitoring  
323 data during the determination of maximum allowable limits for food contaminants.  
324 Total Diet Studies (TDS) continue to provide a valuable source of data to enable the  
325 estimation of background exposure to ubiquitous food contaminants.

326 Examples of surveillance include surveys of chemical contaminants in food, e.g.,  
327 mycotoxins or process contaminants like acrylamide, inorganic contaminants like  
328 metals, and organic environmental contaminants like dioxins. Other examples are  
329 surveys of chemical contaminants from food contact materials and articles intended to  
330 come into contact with food (e.g., cooking utensils), and food additives surveys.

331 A TDS is a continuous market basket-type survey, in which foods representing the  
332 average UK diet are purchased, prepared, and combined into groups of similar foods  
333 for analysis. Food samples representative of the UK diet are purchased throughout  
334 the timeframe from all around the UK. The types and quantities of food purchased are  
335 based on analysis of food consumption data recorded in surveys like the EFS/LCF,  
336 and from trade statistics. The quantities of food are updated each time to reflect  
337 changing eating habits in the UK. Population dietary exposures are estimated by  
338 multiplying the average amount of each food group consumed (based on consumption  
339 data from the NDNS or DNSIYC) by the corresponding chemical concentration in the  
340 food group from the TDS study, then summing across all food groups.

### 341 ***Crème Global software***

342 Data from the NDNS (Bates et al., 2014; 2016; 2020; Roberts et al., 2018) and  
343 DNSIYC (DH, 2013) surveys, as well as the recipes database, are stored within the  
344 software (Crème Software). If an estimate of likely exposure to a chemical in a group  
345 of foods is required, Crème can retrieve information on these foods from the relevant  
346 survey; the recipes database aids this, as it allows a search for specific ingredients.

347 Chemical concentrations can be entered into the program for each group of foods  
348 being considered, and Creme will review each participant's dietary record for the foods  
349 specified. Where a particular food is eaten, consumption data are combined with the  
350 relevant chemical concentration for each person in the survey from all the specified  
351 foods (provided there is a sufficient number of recorded consumers of the food(s) in  
352 question). For chronic exposure, each person's average daily exposure over the length  
353 of the survey (4 days) is calculated. This software can also calculate acute exposure  
354 estimates. If exposure on a bodyweight basis is required, the software can calculate a  
355 person's exposure using their bodyweight as recorded in the survey. The full  
356 distribution of individual exposure is then plotted, and from this distribution summary  
357 statistics (e.g., mean and 97.5<sup>th</sup> percentile) are extracted.

358 The main summary statistics for chronic dietary exposure assessments used for FSA  
359 risk assessments are the mean and 97.5<sup>th</sup> percentile, as well as the number of  
360 consumers and the number of respondents in the population group. This is important,  
361 as consumption or exposure estimates made with a small number of consumers is  
362 unlikely to be accurate. In particular, estimates of the 97.5<sup>th</sup> percentile based on fewer  
363 than 60 consumers are treated with extreme caution, as they may not be  
364 representative of a larger number of consumers. Another summary statistic which may  
365 be used is the median, which can be compared to the mean to give an idea of the  
366 skewness of the data.

367 Most exposure assessments by FSA are consumer-based exposure assessments.  
368 Consumer exposure assessment, in its simplest form, involves combining chemical  
369 occurrence data with consumption data in order to estimate the amount of the  
370 chemical ingested by an individual over a fixed period of time. The benefits of  
371 consumer exposure assessment include the ability to estimate high level (e.g., 97.5<sup>th</sup>  
372 percentile) consumption and the facility to remove non-consumers of the food(s) of  
373 interest from analyses. Considering consumers only is important for foods that are  
374 consumed by a relatively small proportion of the population, allowing specific 'at risk'  
375 population sub-groups to be identified for targeted advice. Population-based exposure  
376 is where 'non-consumers' of the food(s) of interest are not removed from analyses and  
377 consumption/exposure is averaged across all participants in the population group.

378 The software can also calculate the serving size by taking the average amount of all  
379 meals (all amounts divided by the number of eating events). The average serving size  
380 is used to calculate the serving size for the total population and for high consumers.  
381 This may be used to compare to portion sizes given in literature and be used to  
382 estimate exposure.

### 383 ***Dealing with uncertainties in chronic exposure assessment***

384 Sometimes, the chemical occurrence data available may include values below the limit  
385 of detection (LOD) or the limit of quantification (LOQ). In this case the upper and lower  
386 bound approach to exposure assessment is likely to be used.

387 The lower bound (LB) approach is where, if the concentration is <LOD and/or <LOQ,  
388 then the output is assumed to be 0. This results in an underestimation of the exposure.  
389 The upper bound (UB) approach is where if the concentration is <LOD then the output  
390 is assumed to be equal to the LOD and if the concentration is between the LOD and

391 the LOQ, then the output is assumed to be equal to the LOQ. This results in an  
392 overestimation of the exposure. In such a case, two chemical occurrence values, the  
393 LB and the UB values, will be used for the exposure assessment to give a range of  
394 potential exposures.

395 Other uncertainties may be associated with the consumption data. For example, foods  
396 with very few or no consumers recorded have already been mentioned. At the FSA, a  
397 common approach to this type of uncertainty is either to use another similar food  
398 product as a proxy, or to refer to literature or manufacturer's instructions for portion  
399 size estimates, or recommended dosage (for e.g., supplements). In all cases, the  
400 uncertainties associated with exposure assessments are recorded and referred to in  
401 the discussion of the risk assessment.

402 Other types of uncertainty may be associated with the chemical occurrence data, for  
403 example, for food contact materials, there may be limited data on migration into the  
404 food product(s) of interest. In this case, we may have to assume 100% transfer which  
405 would be an extremely conservative assessment. These types of assessment are  
406 taken on a case-by-case basis; again, all uncertainties are recorded and discussed.

#### 407 ***Pros and cons of the model***

408 This section has been included in the descriptions of the approaches for pesticides  
409 and veterinary medicines to discuss the advantages and disadvantages of the models  
410 currently used. However, the FSA does not use one single model but a range of  
411 approaches, as described above.

## 412 **Pesticides - HSE**

### 413 ***General overview***

414 The current HSE approach to the chronic consumer risk assessment of pesticides  
415 relies upon a deterministic assessment using the UK chronic model and the EFSA  
416 PRIMo rev 3.1 model (HSE, no date: Consumer exposure). The estimates of long-  
417 term exposure are calculated based on either pre-registration supervised residue trial  
418 field data, derived in accordance with Regulation 1107/2009, or monitoring data  
419 derived as part of the Great Britain and Northern Ireland monitoring programme, which  
420 is a requirement under Regulation 396/2005.

421 Chronic risk assessment is undertaken to determine pesticide exposure for three  
422 purposes:

- 423 a) Assessment of potential exposure at the time of active substance approval or  
424 product authorisation, based on supervised trial median residue (STMR) values  
425 from residue data for the proposed crop uses only.
- 426 b) Assessment of potential exposure for maximum residue level (MRL) setting and  
427 review (including CODEX MRLs). This will consider all authorised pesticide  
428 uses of the active substance (note: STMR values may not be available for all  
429 uses if an MRL review has not yet taken place).
- 430 c) Assessment of exposure based on monitoring data. A chronic risk assessment  
431 is undertaken on an individual commodity basis, only if sufficient samples of  
432 that commodity have been analysed for that survey (minimum of 12 is  
433 desirable) and where  $\geq 50\%$  of the samples for that commodity have residues  
434 of the same analyte at or above the reporting limit (RL).

435 To address points a) and b) above, the STMR is used for determination of individual  
436 commodity National Estimates of Dietary Intakes (NEDIs) and total dietary intake  
437 calculations (total NEDIs) using the UK model, or for determination of International  
438 Estimated Dietary Intakes (IEDI), using the EFSA PRIMo model. Alternatively, a highly  
439 conservative assessment of the Theoretical Maximum Daily Intake (TMDI) can be  
440 calculated by inserting an MRL value instead of using the STMR.

441 To address point c), for the monitoring programme, chronic risk assessment is  
442 currently undertaken quarterly on a case-by-case basis, using the median residue  
443 determined for an individual commodity to calculate the NEDI. The median residue is  
444 based on all samples surveyed for that commodity in that quarter, including where the  
445 residue was either not detected or was below the RL, but only where an analyte is  
446 found above the reporting level (RL) in  $> 50\%$  of samples.

447 To estimate chronic consumption, the UK model for long term exposure sums the two  
448 highest 97.5<sup>th</sup> percentile commodity intakes and the mean intakes across all the  
449 remaining commodities for each of the consumer sub-groups; this is known as the  
450 Rees-Day approach (HSE, 2006). The 97.5<sup>th</sup> percentile is derived from a distribution  
451 of daily food consumption that individuals have reported throughout the survey (this  
452 does not include non-consumers). See figure 4.

453 **Figure 4:** HSE Rees-Day approach to chronic risk assessment

$$\sum_{x=i}^j \frac{STMR_x \times P97.5_{consumption\ x}}{BW} + \sum_{y=k}^n \frac{STMR_y \times MC_y}{BW}$$

Where:

i, j = two raw agricultural products leading to the highest intake

k, l, m, ...n = remaining raw agricultural commodities consumed

STMR = Supervised Trial Median Residue. Residue value derived from pre-registration data. Note for monitoring data, median residue of monitoring values is used.

P97.5<sub>consumption</sub> = 97.5th percentile consumption of the Raw Agricultural Commodity (RAC) in kg/day based on mean daily intakes of consumers only.

MC = mean consumption of RAC in kg/day derived from mean daily intakes of whole population (consumers and non-consumers).

BW = Body weight (kg)

454

455 A different calculation is used in the EFSA PRIMo rev 3.1 model, which uses mean  
456 consumption for the whole survey (based on consumers and non-consumers) to  
457 calculate chronic exposure. See figure 5.

458 **Figure 5:** EFSA PRIMo rev. 3.1 approach to chronic risk assessment

$$\sum_{x=i}^n \frac{STMR_x \times MC_x}{BW}$$

Where:

i, j, k, ...n = individual raw agricultural products

STMR = Supervised Trial Median Residue. Residue value derived from pre-registration data. Note for monitoring data, median residue of monitoring values is used.

MC = mean consumption of RAC in kg/day derived from mean daily intakes of whole population (consumers and non-consumers).

BW = Body weight (kg)

459

460 The Rees-Day approach is also represented within EFSA PRIMo rev 3.1. It was  
461 included for information purposes only; there was never an intention for it to be used  
462 or relied upon for regulatory decision making by Great Britain (GB) or the EU. It can  
463 be noted that there are some differences in how EFSA has interpreted the UK  
464 consumption data (e.g., not all consumer groups are represented, and mean values  
465 were not used for swine and sheep products), which means there are differences in  
466 the calculation outcome between the EFSA and UK models.

467 Estimated intakes, calculated using either the UK chronic exposure model (NEDI) or  
468 the EFSA PRIMo rev. 3.1 (IEDI), are compared against the ADI for the active  
469 substance. Provided the estimated intakes are less than or equal to the ADI for that  
470 active substance, it is assumed that there is an acceptable low risk to consumer health.

471 It is possible to refine the risk assessment using processing data; however,  
472 refinements are only possible if a commodity is predominantly consumed after being  
473 processed, or there is sufficient consumption data available to capture the combined  
474 consumption via both the raw agricultural commodity (RAC) and any processed  
475 commodities.

476 In addition to chronic risk assessments undertaken for single substances, the data  
477 requirements laid out in Regulation 283/2013 also require a consideration of  
478 cumulative exposure to more than one active substance, when such methods to  
479 assess such effects are available, and where relevant. The current UK and EFSA  
480 models do not have capability built in to do this; however, HSE does consider  
481 combined chronic risk where there is a potential for combined toxicity (assumed to be  
482 additive) and there is combined exposure from two or more pesticides (or relevant  
483 metabolites). The HSE approach (HSE, 2005) to combined toxicity was prompted by  
484 the Working Group on Risk Assessment of Mixtures of Pesticides and Similar  
485 Substances (WIGRAMP), and is outlined in the Pesticide Safety Directorate (PSD)  
486 and Advisory Committee on Pesticides (ACP) guidance<sup>1</sup>: Approach to assessing the  
487 mammalian toxicity (and consumer/operator risk assessment) of two or more  
488 compounds in a pesticide product (formulation). The combined chronic risk  
489 assessment is undertaken using both the UK chronic and EFSA PRIMo models and  
490 follows a three-tier approach.

491 As part of the UK monitoring programme, a consideration of combined exposure can  
492 be undertaken on a case-by-case basis where pesticides found in combination are  
493 known to have additive effects. Generally, this assessment would be an acute  
494 exposure assessment, as the combination of pesticides rarely appear together in large  
495 numbers of samples; however, where there is a need to, i.e., where the combination  
496 of pesticides occurred in  $\geq 50\%$  of samples, a combined chronic risk assessment is  
497 undertaken. The specific pesticide groups for which consideration of combined  
498 exposure (acute or chronic, as required) is currently made include triazoles,  
499 organophosphates/carbamates with known acetylcholinesterase (AChE) inhibition,  
500 mepiquat/chlormequat, folpet/captan, carbendazim/thiophanate-methyl, and specific  
501 combinations of biocides used as disinfectants.

## 502 ***Diet/consumption data***

### 503 **UK chronic risk assessment model**

504 The UK model enables the intakes of ten consumer groups from the consumption of  
505 treated agricultural commodities to be estimated. The current definition of consumer  
506 groups are adult (19-64 years old), infant (6-12 months old), toddler (18 months to 4  
507 years old), 4–6-year-old child, 7–10-year-old child, 11–14-year-old child, 15-18-year-  
508 old child, vegetarian, elderly (own home), and elderly (residential).

509 It should be noted that for future updates to the UK model, the definitions of consumer  
510 groups could change, as new NDNS data will not include respondents in residential  
511 institutions or allow easy separation of vegetarians from the other groups. Average

---

<sup>1</sup> PSD was the predecessor to the current Chemicals Regulatory Division (CRD) and ACP was the predecessor to the current Expert Committee on Pesticides (ECP).

512 bodyweights are used for each of these consumer groups, based on information  
513 submitted as part of the dietary surveys. These are detailed in the following table:

514 **Table 1:** Mean consumer bodyweights used for the ten consumer groups in the UK  
515 chronic exposure model

| Consumer group   | Adult 19-64 years old | Infant 6-12 months old | Toddler 18 months – 4 years old | 4–6-year-old | 7–10-year-old | 11–14-year-old | 15–18-year-old | Vegetarian | Elderly (own home) | Elderly (residential) |
|------------------|-----------------------|------------------------|---------------------------------|--------------|---------------|----------------|----------------|------------|--------------------|-----------------------|
| Body weight (kg) | 76                    | 8.7                    | 14.5                            | 20.5         | 30.9          | 48.0           | 63.8           | 66.7       | 70.8               | 61.6                  |

516

517 The consumption data for the ten consumer groups is provided by FSA and is based  
518 on the NDNS and the DNSIYC from 1986, 1992/93, 1994/95, 1997 & 2001; see section  
519 2 A above for further details. The consumption data are expressed as g/kg body weight  
520 per day for both the mean and 97.5<sup>th</sup> percentile. Information on the number of  
521 consumers who have reported to have eaten a given food commodity within the survey  
522 are also included for each sub-group.

### 523 ***EFSA PRIMo model***

524 This model encompasses a variety of subgroups and survey approaches. Overall, 30  
525 Member State diets for chronic exposure assessments were considered. In addition,  
526 the relevant GEMS/Food Cluster diets relevant for the EU Member States (i.e., Cluster  
527 diet G06, G07, G08, G10, G11 and G15) were incorporated. Mean bodyweights for  
528 each consumer group are used; these data are based on the results of the different  
529 food surveys used to compile the data. These are summarised in the guidance on the  
530 use of EFSA PRIMo revision 3 (EFSA, 2018). It should be noted that the PRIMo model  
531 was later updated to revision 3.1, along with an updated guidance summarising the  
532 modifications (EFSA, 2019).

533 The food consumption data were provided by Member States who derived this  
534 information from national food surveys. Consumption data reported for processed and  
535 composite food was converted by the data provider to the unprocessed raw  
536 agricultural commodity (RAC). The surveys used cannot be considered fully  
537 comparable, as the surveys were performed according to different methodologies;  
538 however, the data are considered appropriate to address risk management questions,  
539 in particular to identify intake concerns for the EU population related to pesticide  
540 residues in food. The food consumption data in EFSA PRIMo revision 3.1 are  
541 structured in accordance with the current version of the food classification used to set  
542 MRLs under Regulation (EC) No 396/2005 (Annex I). The mean consumption data are  
543 expressed as g/kg body weight per day.

### 544 ***Occurrence data***

545 For the purpose of conducting chronic risk assessments, the occurrence data, or  
546 pesticide residue data, originate from two main sources:

- 547 • Pre-registration data
- 548 • Monitoring data

549 ***Pre-registration occurrence data***

550 Pesticide residue data refer to the residue of interest for a pesticide active substance.  
551 This can be either the parent compound, and/or major metabolite(s) which result from  
552 the breakdown of the active substance, or the formation of reaction products. The  
553 pesticide residue which should be quantified in a food commodity is defined by the  
554 residue definition for risk assessment (RD-RA), or the residue definition for  
555 enforcement (RD-Enf). Most of the chronic risk assessments undertaken by HSE rely  
556 on pre-registration data. These data are produced by industry to support the  
557 authorisation of a product or for the approval/renewal of an active substance.

558 Pre-registration data are obtained from supervised field trials. The trials should be  
559 conducted in accordance with the relevant guideline documents and the most critical  
560 good agricultural practice (GAP) in terms of field of use (e.g., indoor or outdoor),  
561 application rate, number of applications, and application timing proposed for the use  
562 of the product for which authorisation is sought.

563 To support the authorisation of a pesticide, either for approval/renewal of the active  
564 substance, or for a use in a new product or on additional crops, a minimum of eight  
565 supervised trials are required for major crops and a minimum of four trials are required  
566 for minor crops. Whether a crop is considered major or minor is based on daily intake  
567 contribution, relevant cultivation area, and/or production. The extrapolation guidance  
568 document<sup>2</sup> provides additional details on this aspect. The supervised residues trials  
569 are used to derive the STMR, which is used in the chronic risk assessment calculation  
570 for determination of the NEDI, total NEDI, or the IEDI. Where it is necessary to  
571 determine the TMDI, the MRL for the active substance is used in place of the STMR.  
572 The MRL is calculated using the OECD MRL calculator<sup>3</sup> and the results of the  
573 supervised residues trials. It is designed to calculate an MRL in the region of the 95<sup>th</sup>  
574 percentile of the underlying residue distribution.

575 ***Monitoring occurrence data***

576 Pesticide residues in food (PRiF) monitoring data are generated as part of the Great  
577 Britain and Northern Ireland monitoring programmes. There is a requirement of Article  
578 29 of the MRL Regulation 396/2005 (and the retained legislation post EU exit) to  
579 undertake a national testing programme, and to take part in a co-ordinated programme  
580 of testing for 34 foods of high consumer interest (over a three-year rolling period).

581 The purpose of the monitoring programme is to:

- 582 a) check that residues do not exceed the statutory MRLs.  
583 b) back up the statutory approvals process for pesticides by checking that no  
584 unexpected residues are occurring in food.

---

<sup>2</sup> Applicable to NI: Technical guidelines on data requirements for setting maximum residue levels, comparability of residue trials and extrapolation of residue data on products from plant and animal origin (SANTE/2019/12752); or applicable to GB: Guidance document on comparability, extrapolation, group tolerances and data requirements for setting MRLs (SANCO 7525/VI/95 Rev. 10.3)

<sup>3</sup> The Organisation for Economic Co-operation and Development (OECD) have developed a MRL calculator with the goal of harmonising the calculation of MRLs across the OECD: [OECD Maximum Residue Limit Calculator - OECD](#)

585 c) check that human dietary intakes of residues in foods are within acceptable  
586 levels.

587 Assessment of human dietary intakes (point c)) are relevant for consideration within  
588 this report.

589 Each year, a programme is drawn up to prioritise the foods under consideration. The  
590 plan is risk based and uses evidence in the public domain about the relative  
591 significance of the food in the UK diet and known incidence of non-compliance with  
592 MRLs, based on various sources, including intelligence from national and international  
593 monitoring programmes. The annual proposal is considered and developed by Defra's  
594 independent expert committee on pesticide residues in food. Comments are sought  
595 from stakeholders via informal liaison.

596 Each year, the monitoring programme analyses around 3350 samples for >390  
597 different pesticides. The samples are analysed by accredited laboratories (ISO17025)  
598 and the residue results are published quarterly, as well as in an annual report. A  
599 smaller number of higher risk surveys are published monthly.

600 When results of the monitoring programme have been confirmed by the laboratories,  
601 HSE assesses the risk to consumer health for every sample that contains a residue at  
602 any level. Most consumer intake assessments are for short-term (acute) exposure  
603 rather than long-term (chronic) exposure. This is because the monitoring data  
604 generally shows the majority of samples contain residues below RL and so chronic  
605 exposure would not present a concern.

606 NB: Residues below the RL are also not screened for acute risk. The RL is generally  
607 sufficiently low enough to ensure that any acute (or chronic) risk could be identified for  
608 the active substances or metabolites included in the monitoring programme.

### 609 ***Description of uncertainties***

610 There are some uncertainties common to both the UK chronic exposure model and  
611 the EFSA PRIMo model. Where an uncertainty relates only to one of the models used,  
612 this will be described under the separate sub-headings below.

#### 613 *Uncertainties common to both UK and EFSA models*

614 Both models used for chronic risk assessment are deterministic; as such, they can  
615 only take limited account of variability. They use fixed values for toxicity (hazard) and  
616 exposure, producing a single measure of risk; they do not allow a prediction of the  
617 level of protection, e.g., estimating how often a percentage of the population that  
618 exceeds a regulatory trigger will occur. Any uncertain or variable factors are fixed to  
619 worst-case values or dealt with subjectively using expert judgement. If probabilistic  
620 methods of risk assessment were used, these could take account of the variability and  
621 uncertainty that exists in the real-world situations, and potentially provide an improved  
622 basis for decision making. However, further work is needed to develop and implement  
623 probabilistic models, and these are not currently available.

624 The measured level of a pesticide or metabolite in a food commodity can be below the  
625 LOD or the LOQ. The data requirements (Reg. 283/2013) state that an LOQ shall be  
626 determined and reported for each analyte for the analytical methods used for risk  
627 assessment, whereas there is no legal requirement to specify the LOD. If the

628 concentration is >LOD but <LOQ, then the sample is positive but cannot be reliably  
629 quantified. Where the concentration is determined to be <LOQ, then the output is  
630 assumed to be at the LOQ for the purpose of chronic risk assessment.

631 This is likely to result in an overestimation of the exposure but is considered to be  
632 acceptable as a conservative approach to show that there will be no risk to consumers.  
633 The use of the LOQ in chronic risk assessment is considered justified, as HSE does  
634 not have robust information about authorisations in other countries which give rise to  
635 residues below the LOQ. Where an MRL is set at the LOQ, it does not necessarily  
636 mean there are no authorised uses of that pesticide on that commodity; an MRL could  
637 be set at the default LOQ (0.01 mg/kg) where there are no authorised uses, or where  
638 the authorised use leads to residues below the LOQ; hence, while assuming residues  
639 are at the LOQ is likely to overestimate the exposure, disregarding the LOQ values in  
640 the overall chronic exposure could underestimate the exposure, i.e., where a residue  
641 is present in the food above the LOD but below the LOQ.

642 The method of gathering consumption data can result in uncertainties relating to the  
643 representativeness of the data set, i.e., where some foods have very low numbers of  
644 consumers recorded. In this situation, as part of both the pre-registration assessment  
645 and in the monitoring programme, it is common to use a surrogate food which would  
646 be considered to have a similar range of consumers and would be consumed in a  
647 similar portion size and manner (e.g., potato may be used as a surrogate for yam due  
648 to a low number of consumers in some sub-groups for yam). A judgement on the  
649 suitability of a surrogate food would be based on literature, or through consultation  
650 with FSA.

651 Similarly, extrapolation between crops with similar growing practices, pest problems,  
652 and morphology can be conducted. Field trial residue data from one or several  
653 representative commodities can be extrapolated to related commodities in the same  
654 commodity group or subgroup for which trials have not been conducted. Specific  
655 extrapolations are allowed, based on the extrapolation guidelines  
656 (SANTE/2019/12752, relevant to NI, or SANCO 7525/VI/95 Rev. 10.3, relevant to GB).  
657 Where a surrogate food group or extrapolation has been used, this would be recorded  
658 within the assessment, and additional uncertainty factors would usually not be  
659 required.

660 For the assessment of chronic risk as part of the pre-registration process, or when  
661 using data derived from the monitoring programme, there can sometimes be small  
662 sample sizes; typically, only four residues trials are required to support an  
663 authorisation for use on a minor crop, and only eight trials for a major crop. In the  
664 monitoring programme, the number of samples analysed per quarter can sometimes  
665 be <10. This could mean that the data do not show the full range of possible residue  
666 values to which a consumer may be exposed.

667 For some calculations, default factors such as variability, conversion, or processing  
668 factors are used to refine the risk assessment. As these are default factors and not  
669 always specific to the active substance (or metabolite(s) where relevant) or crop, this  
670 can add to uncertainty in the calculation.

671 Neither the FSA nor the EFSA models can account for case-specific non-standard  
672 uncertainties. These can arise due to the available data being substandard, such as  
673 not being generated in accordance with the appropriate guidance documents, not  
674 having robust processing or conversion factors, or where analytical methods used to  
675 determine the residue present have not been fully validated for all components of the  
676 defined marker residue. The impact of the non-standard uncertainties on the outcome  
677 of the chronic exposure assessment must be assessed, usually by 'expert judgement',  
678 on the case-specific scenario.

679 The current procedure for conducting chronic risk assessment for pre-registration data  
680 does not routinely account for exposure to low levels of chemical mixtures which could  
681 cause adverse effects due to additive or synergistic interactions; the potential for  
682 interaction or toxic effects of different substances in combination is not regularly  
683 addressed by the standard single substance assessment approach. However, for  
684 products containing more than one active substance which are known to have a similar  
685 mode of action or target organ, a basic combined risk assessment is undertaken.  
686 There is limited understanding of human exposure to low levels and mixtures of  
687 chemicals; as such, the exposure is routinely calculated separately for each active  
688 substance. An exception to this is the risk assessment undertaken as part of the  
689 monitoring programme, where both chronic and acute combined risk assessments can  
690 be undertaken on a case-by-case basis for specific groups of active substances found  
691 in combination in a sample where there are known additive or synergistic effects.

692 The chronic assessment in the UK also does not account for 'aggregated risk', the risk  
693 to an individual or population group who may come into contact with a chemical from  
694 multiple sources. This could be a result of exposure of operators or by-standers during  
695 the application of a pesticide, plus any potential exposure from the consumption of the  
696 active substance (or metabolite) residues in foods.

#### 697 ***UK chronic risk assessment model***

698 In the UK model, some uncertainty comes from the consumption data used. The  
699 consumption data currently used are relatively old and may not account for changes  
700 to consumer habits, diets, and typical bodyweights. Detailed consumption data are not  
701 available in the UK model for all food products included in the current version of the  
702 food classification used to set MRLs for pesticides under Regulation (EC) No 396/2005  
703 (Part 1 of the GB MRL statutory register or for the EU, Part A and B of Annex I to this  
704 regulation), including some commonly eaten and readily available foods. Where a food  
705 product is not included, it may be reasonable to use a surrogate.

706 It is noted that more modern consumption data are available in the form of NDNS  
707 survey data; however, at this time, the necessary steps have not been undertaken to  
708 allow incorporation of these data into the UK models.

709 Although refinement of consumption data is possible, it can be difficult to make  
710 meaningful refinements to the exposure assessment due to a lack of detailed  
711 consumption data, specifically considering commodities commonly consumed after  
712 processing, i.e., consumption data for raw vs. cooked foods, such as tomato,  
713 cauliflower, or carrot.

#### 714 ***EFSA PRIMo model***

715 Food consumption data used in the EFSA PRIMo are not fully comparable to those  
716 used in the UK model. This is due to significant differences in the design of the surveys  
717 submitted by different EU Member States when compiling the data. Differences in the  
718 statistical analyses of the consumption data, e.g., the methods used for calculation of  
719 mean or high percentile consumption, are also not standardised throughout the  
720 different surveys. This is one reason why EFSA plan to only use data from their  
721 comprehensive food database when revision 4 of the EFSA PRIMo model is  
722 developed; all survey data from all Member States will have to meet certain  
723 requirements, which will reduce some of these uncertainties.

## 724 ***Pros and cons of the model***

### 725 ***Pros***

726 The models are straightforward to use, they are not resource intensive, and they  
727 provide simple, conservative calculations which give a clear indication of whether a  
728 pesticide use will lead to an unacceptable risk to consumers.

### 729 ***Cons***

730 Consumption data are not available for all food products listed in the EU food  
731 classification used for pesticides (Part A of Annex I of Regulation (EC) No 396/2005).

732 No detailed consumption data are available for minor food products listed in Part B of  
733 the EU food classification used for setting MRLs for pesticides.

734 The models do not allow for a more refined probabilistic approach to risk assessment  
735 which may be more reflective of real life.

## 736 ***Other international approaches***

### 737 ***JMPR approach***

738 The Joint FAO/WHO Meeting on Pesticide Residues (JMPR) approach to chronic risk  
739 assessment combines available residue data with cultural dietary information to  
740 estimate potential residue intake by consumers. The consumer is considered to be  
741 adequately protected when estimated dietary intake (EDI) of pesticide residues does  
742 not exceed the ADI; however, percentages above 100% of the ADI are not necessarily  
743 interpreted as giving rise to a health concern, due to the conservative assumptions of  
744 assessments.

745 The JMPR model (Version 4, 2019) is a deterministic model which incorporates 17  
746 cluster diets. These cluster diets are based on food balance sheets and CODEX  
747 commodity codes and are designed to cover regions with similar dietary patterns from  
748 around the world. For information, the UK comes under the cluster G07, along with 9  
749 other countries. The GEMs (global environmental monitoring and assessment  
750 programme) cluster diets relevant to EU countries are also included in the EFSA  
751 PRIMo model. The default adult bodyweights used in the IEDI calculations are 55 kg  
752 for cluster G09 and 60 kg for all others.

753 Long term dietary intakes are calculated by multiplying the residue concentrations  
754 (STMRs, STMR-Ps (STMR-processed commodities)) by the average daily per capita  
755 consumption estimated for each commodity, based on the GEMS/Food diets, and  
756 summing the intakes for each food; see figure 6.

757 **Figure 6: JMPR approach to chronic risk assessment**

$$IEDI = \sum (STMR_i \times F_i)$$

Where:  
F<sub>i</sub> = GEMS/Food regional consumption of food commodity i  
Based on mean per capita intake from food balance (e.g., production minus exports plus imports).  
STMR<sub>i</sub> (or STMR-P<sub>i</sub>) = STMR (or STMR-P) for food commodity i

758

759 Using the JMPR approach, when the pesticide is also used as a veterinary medicine,  
760 and MRLs are established for animal commodities, the residues from use as a  
761 veterinary medicine should also be accounted for in the IEDI calculation.

762 The JMPR model is used for:

- 763 • Assessment of specific substances where there is a potential public health  
764 concern.
- 765 • Periodic review of pesticide active substance data and current MRLs.
- 766 • Assessment of potential exposure when setting new MRLs.

767 The JMPR can only evaluate data relating to uses that are already registered in at  
768 least one CODEX Member State.

769 Like the UK chronic exposure model and the EFSA PRIMo rev. 3.1 model, the JMPR  
770 approach shares the same common uncertainties, i.e., the model is deterministic,  
771 residues determined to be >LOD but <LOQ are assumed to be at the LOQ for the  
772 purpose of the calculation\*, there can be limitations in the data, such as low number  
773 of consumers included in a survey, or small sample sizes, and the model cannot easily  
774 account for combined or aggregate risk (see section 'Description of Uncertainties',  
775 above, for further description). In addition, the JMPR approach comes with its own  
776 uncertainties.

777 \* An exception to this is where there is evidence that there is a zero residue situation;  
778 in this case they will include zero in the calculation. JMPR only assesses exposure  
779 from the uses it has considered and recommended MRLs for; hence, if it has not  
780 recommended a CODEX Limit (CXL) then there is no automatic MRL for all other crops  
781 at the LOQ.

782 The model does not contain accurate information on the consumption of processed vs  
783 unprocessed foods, making any additional refinement difficult.

784 The model uses the GEMs cluster diets, in which the food available per capita in a  
785 country is estimated from trade balance sheets (i.e., food produced, imported, and  
786 exported). Specifically for the chronic model, only data from the GEMs cluster diets  
787 are included. These cluster diets do not give details on which population groups are  
788 consuming the food, particularly children, which are often the critical groups for  
789 exposure owing to their high consumption relative to their body weight. As such, it is  
790 not suitable for estimating children's exposure, or for assessing less than lifetime  
791 dietary exposure.

792 ***EU monitoring/EFSA – Chronic risk assessment***

793 NB: The following chronic risk assessment scenario is discussed as it is relevant to  
794 the GB and Northern Ireland (NI) monitoring programme, which is obliged by Art. 32  
795 of Regulation 396/2005 to conduct and publish an Annual Report on pesticide  
796 residues, including information on the analysis of chronic and acute risks to the health  
797 of consumers from pesticide residues.

798 Previously, the UK monitoring programme has not had to publish its own annual report,  
799 as it was part of the EU programme, and as such has not had to consider chronic  
800 exposure in the same depth as that which is covered by the EU; however, since the  
801 UK left the EU, this will be a requirement, and as such it is relevant to consider how  
802 EFSA have conducted chronic risk assessments to understand if a similar approach  
803 should be undertaken by GB and NI.

804 Like the GB and NI monitoring programme, there is an EU-coordinated programme  
805 (EUCP) examining pesticide residue levels in foods on the European market, in  
806 accordance with Regulation (EC) No 396/2005. To fulfil the requirement of Art. 32 of  
807 this Regulation, EFSA publishes its annual report based on data from the official  
808 national control activities carried out by EU Member States.

809 In the recently published annual report (EFSA, 2021), EFSA estimated the chronic  
810 exposure to pesticides for which residue concentrations were reported for all food  
811 products, using the PRIMo rev. 3.1 model.

812 The purpose of the chronic exposure assessment was to estimate the dietary  
813 exposure to pesticides from food over a long timeframe, with the aim of predicting  
814 lifetime exposure to pesticide residues in the diet. The calculation was based on a  
815 deterministic approach developed by JMPR (FAO, 2017), where the mean measured  
816 pesticide concentration is multiplied by the mean commodity's daily intake  
817 consumption per capita and the results for all commodities are summed within a  
818 particular dietary plan.

819 Three scenarios were calculated:

- 820 • The lower bound scenario, which assumes that if the residue is not quantifiable,  
821 it is not present in the food product analysed.
- 822 • The adjusted middle bound scenario, which assumes that even if not quantified,  
823 residues are present at the level of half the LOQ.
- 824 • The adjusted upper bound scenario, which assumes that even if not quantified,  
825 residues are present at the level of LOQ (for all pesticide/commodity  
826 combinations for which residues >LOQ were found in at least one sample).

827 Several assumptions including, but not limited to, availability of consumption data,  
828 validated LOQs of the relevant methods and residues being reported in accordance  
829 with the RD-Enf were considered by EFSA when conducting the chronic risk  
830 assessment; please refer to the 2019 EU report on pesticide residues in food (EFSA,  
831 2021) for full details.

832

833

## 834 **Veterinary Medicines – VMD**

### 835 ***General overview***

836 Dietary exposure assessments in the context of veterinary medicinal products (VMPs)  
837 are only conducted for the purpose of establishing MRLs for pharmacologically active  
838 substances used in VMPs for food producing species (i.e., animals raised and kept for  
839 food production). The data requirements are described in Commission Regulation  
840 (EU) 2018/782, which establishes the methodological principles for the risk  
841 assessment and risk management recommendations referred to in Regulation (EC)  
842 No 470/2009. The approach described in this Regulation is used for chronic dietary  
843 exposure only, as currently, acute exposure is not considered when establishing MRLs  
844 for VMPs in the UK.

845 The TMDI approach is the usual dietary exposure calculation method used by the  
846 VMD. This methodology would fit somewhere in between Tiers 1 and 2 of the r tiered  
847 approach to dietary risk assessment, as presented in Figure 1. A standard food basket  
848 is used as a model for the food consumption of a 60 kg adult, with MRLs expressed  
849 as residue concentration in those food items included in the food basket (see detailed  
850 explanation below). The individual food item TMDI is calculated for all edible tissues  
851 and commodities which have an assigned MRL, and all these individual TMDIs are  
852 then summed. The resultant total TMDI for all edible tissues and commodities must  
853 not exceed the ADI. Otherwise, lower MRLs need to be established.

854 MRL applications usually focus on edible tissues (i.e., muscle, fat, liver, and kidney);  
855 however, potential uses in the commodities milk, eggs, and honey, are also  
856 considered. Since it is not possible to predict with certainty the future use of a  
857 substance in other food-producing species, and with a view to increasing availability  
858 of VMPs as a general principle, it is considered that unless MRLs are proposed in all  
859 food commodities included in the standard food basket, an adequate portion of the  
860 ADI shall remain unused (i.e., it is left for use for the other commodities, should it be  
861 necessary in the future).

862 In the case of active substances also used as plant protection products  
863 (PPPs/pesticides), a guidance figure for the portion of the ADI that may be reserved  
864 for VMP use is 45%. Where the existing PPP authorisation allows, and sufficient data  
865 are available on intake from PPP use, it may be possible to allocate a larger portion to  
866 VMP use without exceeding the ADI. In order to identify the proportion of the ADI that  
867 is available for VMP use, the MRLs approved for the PPP use are taken into account.

868 For substances used as biocides in animal husbandry, the Committee for Veterinary  
869 Medicinal Products (CVMP) 'Guideline on risk characterisation and assessment of  
870 maximum residue limits (MRLs) for biocides' (CVMP, 2015) is followed. A stepwise  
871 procedure is used to determine whether an MRL assessment is required. If the  
872 estimated exposure of an animal (summed over all routes: oral, dermal, and inhalation)  
873 exceeds the trigger value of 4 µg/kg bw, established by the EU Biocides Technical  
874 Meeting, then a more detailed consideration of the potential for residues in edible  
875 products is required, and an estimation of a worst-case consumer exposure (WCCE)  
876 is undertaken and compared to the ADI. The WCCE uses worst case assumptions of  
877 the internal dose received by the animal and combines them with the standard food

878 basket. If it is indicated that exposure reduction measures are needed to ensure that  
 879 consumer exposure remains below the ADI, then a formal MRL procedure is triggered.  
 880 However, as is the case in most instances, if the total exposure is below the trigger  
 881 value, or if the WCCE demonstrates that exposure reduction measures are clearly not  
 882 needed to keep consumer exposure below the ADI, then there will be no need for an  
 883 MRL evaluation. No biocide-specific MRLs have yet been established, either in the EU  
 884 or in the UK.

885 A 'No MRL required' classification may be recommended in those cases where the  
 886 establishment of numerical MRLs is not necessary for the protection of the consumer.  
 887 In such cases, it is concluded that consumer exposure to residues will always remain  
 888 at safe levels, i.e., <ADI or other alternative HBGV h (e.g., tolerable daily intakes or  
 889 recommended daily allowances). Similarly, substances (most often excipients) that  
 890 are demonstrated to have no pharmacological activity at the dose given to the  
 891 animal(s) being treated are regarded as being out of scope of the MRL legislation, and  
 892 therefore an MRL evaluation is not considered to be needed for these substances  
 893 (although data are required to confirm a lack of pharmacological activity, and a  
 894 regulatory procedure has been established for this). In cases where numerical MRLs  
 895 are not required, dietary exposure can still be calculated using the standard food  
 896 basket and a realistic worst-case estimation of the levels of residues in edible  
 897 tissues/commodities after the use of a product following the recommended dosing  
 898 regimen.

899 ***Diet/consumption data***

900 It is assumed that the consumer will eat a standard food basket of animal-derived  
 901 products every day. The standard food basket represents the (conservatively  
 902 estimated) consumption of a 60 kg adult, which is the only age group considered when  
 903 carrying out the chronic dietary exposure assessment. This standard food basket is  
 904 shown in the table below:

905 **Table 2:** The standard food basket for VMPs

| Mammals  |          | Poultry                             |       | Fish                                   |       | Bees  |        |
|--|----------|-------------------------------------|-------|--|-------|-------|--------|
| Muscle   | 300 g    | Muscle                              | 300 g | Muscle and skin in natural proportions | 300 g | Honey | 20 g** |
| Fat  | 50 g*    | Fat and skin in natural proportions | 90 g  |  |       |       |        |
| Liver  | 100 g    | Liver                               | 100 g |  |       |       |        |
| Kidney   | 50 g     | Kidney                              | 10 g  |  |       |       |        |
| Milk   | 1 500 ml | Eggs                                | 100 g |  |       |       |        |
| *Fat and skin in natural proportions for pigs. **JECFA <sup>4</sup> uses 50 g. |          |                                     |       |  |       |       |        |

906

907 MRLs are proposed for the relevant edible tissues and/or commodities, considering  
 908 the proposed use of the substance that is being evaluated. For the edible tissues, it is

<sup>4</sup> Joint FAO/WHO Expert Committee on Food Additives

909 assumed that only one of the major groups is consumed per day (i.e., mammal, fish,  
910 or poultry; not all three).

### 911 **Occurrence data**

912 The levels of residues used in the risk characterisation are the MRLs for each of the  
913 different tissues/commodities.

914 Although the VMD administers a residues control programme for residues of  
915 veterinary drugs in products of animal origin (POAO), the data acquired do not feed  
916 back into risk assessments, other than where there are large exceedances of the  
917 authorised MRLs, and in these cases, FSA is the responsible authority.

### 918 **Theoretical Maximum Daily Intake**

919 The TMDI is calculated using the standard food basket shown above and assumes  
920 that residues are present in all food commodities at the respective MRLs. The  
921 calculation usually includes factors to convert the concentration of residues found in  
922 the depletion studies (marker residue) to total residue concentrations (i.e., all residues,  
923 including the parent molecule and all metabolites). This is done by assigning a marker  
924 residue, which is usually the parent compound and/or one of its metabolites, and a  
925 ratio between this marker residue and the total residue. The total TMDI is calculated  
926 by summing the separate TMDIs for each tissue, which are obtained using the  
927 following equation:

$$\text{Amount per edible tissue or product} = \frac{\text{Proposed MRL} \times \text{Daily consumption}}{\text{Ratio of the marker to total residue}}$$

928

929 If the total TMDI is higher than the ADI (or the portion of the ADI reserved for veterinary  
930 use) for the substance, then lower MRLs need to be proposed, such that the total  
931 TMDI is <ADI.

### 932 **Description of uncertainties**

933 Given that neither the consumption figures nor the residue concentration values are a  
934 result of direct measurements, the uncertainty associated with this methodology  
935 comes from lack of data sampling rather than from variability in the data, or generated  
936 by the analytical methodologies, sampling techniques or population surveys.  
937 Therefore, uncertainty cannot be characterised.

938 In the case of dietary intake, the standard food basket is likely an overestimation of  
939 what an adult person will eat every day, although high-end consumers of a particular  
940 food item, certain age groups (e.g., infants), or consumers of edible  
941 tissues/commodities that are consumed less by the general UK population (and  
942 therefore no MRLs are established), may have their exposure underestimated using  
943 this calculation.

944 With regard to residue concentrations in food, the use of MRLs as the exposure level  
945 is an overestimation of the chronic dietary exposure, given that food derived from  
946 animals will generally have residue levels which are well below the established MRLs.

947 It is considered that, even if uncertainty cannot be characterised, in general, the TMDI  
948 approach will overestimate the dietary exposure to residues from veterinary medicines  
949 in most subpopulations, and thus be protective of the whole population.

950 It should be noted that there is no need to refine the dietary exposure assessment at  
951 the point of setting MRLs, as when authorising VMPs for use in food-producing  
952 species, withdrawal periods (the time between the final treatment and the day of  
953 slaughter or collection of milk/eggs/honey) are established that ensure all residues are  
954 <MRLs.

955 ***Pros and cons of the model***

956 ***Pros:***

957 The most obvious benefit of using the TMDI method is its simplicity, as no further  
958 calculations are needed for the dietary consumption figures, nor the occurrence of  
959 residues in food.

960 As mentioned earlier, the TMDI will generally overestimate the dietary exposure;  
961 therefore, this method is useful to estimate the worst-case dietary exposure, thus  
962 guaranteeing consumer safety with a wide margin of safety when establishing MRLs.  
963 This overestimation also enables its use as a screening methodology in a tiered  
964 approach.

965 ***Cons:***

966 The standard food basket does not represent the real consumption as accurately as  
967 other models, usually resulting in an overestimation of the dietary intake. However,  
968 as explained above, consumers with unusual dietary habits may be under-represented  
969 with this method.

970 Only muscle, liver, kidney, fat, milk, eggs, and honey are considered when establishing  
971 MRLs for substances used in veterinary medicine. Other edible tissues (such as lungs  
972 or intestines) are not considered with this methodology, and minorities consuming  
973 these commodities are not represented in the exposure calculation.

974 ***Other international approaches***

975 The Joint FAO/WHO Expert Committee on Food Additives (JECFA), which provides  
976 recommendations for MRLs to CODEX, has adopted two dietary exposure calculation  
977 approaches based on a standard food basket containing specific quantities of muscle,  
978 liver, kidney, fat, eggs, milk, and honey; the TMDI described above, and the Estimated  
979 Dietary Intake (EDI).

980 In addition, two new approaches to dietary exposure calculation, using actual food  
981 consumption data, the Global Estimate of Chronic Dietary Exposure (GECDE) and the  
982 Global Estimate of Acute Dietary Exposure (GEADE), have been proposed recently  
983 and are starting to be used for exposure calculations when deriving new MRLs. The  
984 GECDE is explained below; acute dietary exposure is not considered under the remit  
985 of this project.

986 JECFA also considers that when there are no detectable residues in a particular tissue  
987 in the depletion studies at the timepoint on the depletion curve corresponding to the  
988 MRL recommendations, the guidance MRLs (based on 2 x LOQ) should not be  
989 included in the total TMDI calculation.

990 JECFA uses 60 kg as the bodyweight for an adult, 15 kg as the bodyweight for a child,  
991 and 5 kg as the bodyweight for an infant.

992 EDI: The calculation is essentially the same as that used for the TMDI, except that the  
993 median residue concentration at the timepoint that was used to derive the MRL is used  
994 in the calculation, instead of the MRL itself. JECFA considers that the median residue  
995 is more representative of potential exposure than the upper limit represented by the  
996 MRL. This method can only be used where there are sufficient residue data for all food  
997 basket items at the timepoint associated with the MRL to provide median  
998 concentrations to use in the calculation.

999 GECDE: The GECDE assumes that, in the longer term, an individual would be a high-  
1000 level consumer of only one category of food and that their consumption of other foods  
1001 containing the residue would remain at the population average (total population).  
1002 Therefore, the GECDE uses two different types of consumption data, combined with  
1003 median occurrence data, to estimate chronic dietary exposure.

1004 Firstly, the highest exposure from all the relevant foods at the 97.5<sup>th</sup> percentile of  
1005 consumption is selected. This value is derived from chronic consumers of the food  
1006 only, rather than from the whole population. The choice of a high percentile, such as  
1007 the 97.5<sup>th</sup>, is justified by using a single commodity (instead of two, as for other food  
1008 chemicals).

1009 Secondly, the mean dietary exposures from all the other relevant foods are then added  
1010 to estimate total exposure. The mean dietary exposure is derived from the total  
1011 population; in other words, non-consumers of each food item are included in these  
1012 calculations.

1013 Food consumption data is estimated through food consumption surveys at an  
1014 individual, household, or population level, or approximated through food production  
1015 statistics at the population level only. There are several food consumption databases  
1016 that can be used for this purpose, such as [FAOSTAT](#), [GEMS/Food](#), [CIFOCOs](#), or  
1017 [GIFT](#). In addition to the general population and children, dietary exposure of infants  
1018 can also be estimated.

1019 **3. Discussion**

1020 ***Differences in approach and the reasons for them***

1021 There are differences in the current approaches to chronic dietary risk assessments  
1022 undertaken by FSA, HSE, and VMD, as clearly shown in Section 2. The reasons for  
1023 this are partly historical. The food basket approach used by VMD originated in the  
1024 early assessments of VMP residues by JECFA in the 1980s (WHO, 1988; 1989).  
1025 JECFA did not have access to accurate food consumption data, particularly at the  
1026 international level, considering differences in dietary habits around the world, but  
1027 aimed to use high consumption figures for each edible product.

1028 JECFA later saw limited consumption data submitted by several countries. These data  
1029 were not comparable due to differences in the methodologies used; however, JECFA  
1030 concluded that these data indicated that the consumption figures in the food basket  
1031 were realistic but conservative (WHO, 1993). JECFA's approach was widely followed  
1032 by different countries and regions of the world, which has allowed some harmonisation  
1033 in approach, and in the MRLs set. This approach was seen as sufficiently  
1034 conservative, and since the aim was to be protective of consumer safety, rather than  
1035 to accurately assess dietary exposures, there has to date been no move away from  
1036 this approach by the VMD.

1037 The food basket approach is still used as an initial screening approach by JECFA,  
1038 which has recently additionally started to use the GECDE and GEADE approaches,  
1039 using consumption data, as described in Section 2. When establishing MRLs, JECFA  
1040 still use the EDI approach by preference, and then confirm that the ADI will be unlikely  
1041 to be exceeded, using the GECDE methodology. MRLs are not adjusted downwards  
1042 in light of this.

1043 In the case of pesticides, the JMPR has long used average food consumption data  
1044 generated from food balance sheets, as this was considered the best source of data  
1045 available to make international comparisons. This was reflected in WHO guidelines on  
1046 exposure assessment for pesticide residues (WHO, 1989b). These guidelines  
1047 recommended that, at the national level, the most relevant source of food consumption  
1048 data should be used. However, they stated that an effort should be made to reflect  
1049 long-term food consumption habits, and not day-to-day variations, in order to permit a  
1050 valid comparison to the ADI and, therefore, recommended that average daily food  
1051 consumption values be used.

1052 These food consumption figures were multiplied by MRLs, in a TMDI approach. In later  
1053 years, the TMDI approach started to be used primarily as an initial screen, to separate  
1054 those pesticides for which there are no concerns for long term intake from those which  
1055 require further consideration. The IEDI approach, or NEDI at the national level, which  
1056 uses median residue levels from supervised trials, rather than MRL levels, is now  
1057 largely used by the JMPR (WHO, 1997).

1058 Revised WHO guidelines recommended that exposure assessments conducted at the  
1059 national level should consider subgroups of the population which may be more  
1060 susceptible to certain toxic effects, such as children, pregnant women, and the elderly,  
1061 and that 'authorities may wish to consider possible risks to subgroups of the population

1062 which habitually consume greater quantities of individual foods than are shown on  
1063 food balance sheets' (WHO, 1997).

1064 While other European countries continued to use mean food consumption figures from  
1065 dietary surveys, the UK estimated intakes for high level consumers. In the 1990s, it  
1066 developed the Rees-Day model to share with stakeholders, which would provide rapid,  
1067 non-resource-intensive estimates of high-level chronic exposure. Example  
1068 assessments conducted at that time showed the model provided a good estimate of  
1069 the 97.5<sup>th</sup> percentile intake, estimated using complete consumption data for each  
1070 consumer, similar to that currently used by FSA, and described as a more complex  
1071 deterministic approach in Section 2. Most example estimates fell within 100 - 130% of  
1072 the intake estimated using the more complex deterministic approach, with the full  
1073 range being 90 - 180%. The model was published online, making it available to  
1074 applicants and other stakeholders. It is currently available online at  
1075 [https://www.hse.gov.uk/pesticides/pesticides-registration/data-requirements-](https://www.hse.gov.uk/pesticides/pesticides-registration/data-requirements-handbook/consumer-exposure.htm)  
1076 [handbook/consumer-exposure.htm](https://www.hse.gov.uk/pesticides/pesticides-registration/data-requirements-handbook/consumer-exposure.htm).

1077 FSA takes a tiered approach to exposure assessment, as described in Section 2. Most  
1078 assessments are either simple conservative assessments, which are not continued to  
1079 higher tier assessments due to no concern being identified, or complex deterministic  
1080 assessments. The latter use Creme Global software. Consumption data from dietary  
1081 surveys are combined with single values for the concentration of the chemical in each  
1082 food (usually the mean) to estimate intakes for each consumer in a population group.  
1083 A distribution of exposures is generated from which statistics such as the mean and  
1084 97.5<sup>th</sup> percentile are extracted. The 97.5<sup>th</sup> percentile is used to represent high level  
1085 consumption. Exposure assessments are conducted for different age groups  
1086 depending on the requirements of the risk assessment, but usually at least for adults  
1087 and young children. This approach has required investment in the dietary surveys, the  
1088 development of a recipes database, and the Creme Global software. While these  
1089 require significant resources, the individual exposure assessments subsequently  
1090 conducted are not themselves resource intensive. The use of probabilistic modelling  
1091 is considered on a case-by-case basis, but to date has not been used routinely by FSA  
1092 in chronic dietary exposure assessment.

1093 One additional difference is that HSE requires the consumption data it uses to be  
1094 expressed on an RAC basis, since the pesticide residue data used in risk assessments  
1095 are primarily from RACs, whereas the consumption data the FSA uses are not  
1096 expressed in this way as the chemical occurrence data being used in the risk  
1097 assessment are often from foods in a more processed form or from foods that have  
1098 been prepared for consumption (e.g. in Total Diet Studies). Thus, food consumption  
1099 data from dietary surveys must be adjusted to RAC equivalents before they can be  
1100 used by HSE.

### 1101 ***Dealing with uncertainties***

1102 There is always some uncertainty associated with an exposure assessment, e.g., a  
1103 shortage of knowledge about specific factors in the exposure assessment. It is  
1104 important in exposure assessment to distinguish between uncertainty and variability.  
1105 Variability refers to differences within a population and cannot be reduced, whereas  
1106 uncertainty refers to a lack of knowledge, which may be reduced by further

1107 investigation. Nonetheless, variability is one of many sources of uncertainty in  
1108 exposure assessment, as illustrated by several of the factors described below.

### 1109 **How uncertainties can differ at different tier levels**

1110 The type and complexity of the exposure assessment that is performed will determine  
1111 the amount of uncertainty that occurs in the model. When performing lower-tier  
1112 assessments (as described in Figure 1), the models will usually include a greater  
1113 amount of uncertainty, given that the parameters used in the calculations are usually  
1114 not based on sampling techniques, and therefore their variability cannot be estimated.  
1115 For example, using an MRL as a chemical concentration value, or using a standard  
1116 food basket as a surrogate for the dietary consumption figures, does not provide any  
1117 information on how these parameters are distributed in the population. Therefore, their  
1118 variability cannot be estimated or accounted for, leading to higher uncertainty in the  
1119 model. By way of accounting for such uncertainty when performing lower tier  
1120 assessments, uncertainty factors may be considered, or, as seen in the approach  
1121 taken by the VMD when assessing consumer exposure to VMPs, conservative  
1122 assumptions may be made with regard to setting (default) values used for  
1123 consumption inputs (for example, with the standard food basket) and/or with regard to  
1124 the potential residue levels present in the commodity (such as by assuming the MRLs  
1125 are reached). Such assumptions ensure that subsequent exposure calculations  
1126 represent a worst-case scenario and ensure the safety of consumers.

1127 On the other end of the spectrum, when performing more complex dietary exposure  
1128 assessments at higher-tier levels (e.g., probabilistic modelling), the variability in the  
1129 data can be estimated and quantified, thereby reducing the uncertainty of the model.  
1130 The uncertainty can be eliminated by performing direct measurements or using  
1131 biomonitoring techniques for very specific risk assessments. The use of uncertainty  
1132 factors in these cases may not be required, or if it is, these factors can be quantified  
1133 using the estimated variability in the data.

1134 Given that lower-tier assessments usually require fewer resources to be performed,  
1135 these can be used as screening tools, even though they will provide less accurate  
1136 results. If needed, the calculations can then be refined and uncertainty reduced by  
1137 moving onto a higher tier, or by collecting higher-quality data with more sensitive  
1138 methodologies. In any case, a description and, if possible, an estimation of the  
1139 uncertainty of the model used should always be performed, as this can inform the risk  
1140 manager whether to expend more resources to perform higher tier assessments.

### 1141 **Uncertainty from food consumption information**

1142 Misreporting (under-reporting is more common than over-reporting) is a well-  
1143 recognised problem common to all dietary surveys. There are two aspects to  
1144 misreporting, the 'observation' effect, whereby survey participants change their eating  
1145 habits as a result of being asked to report their consumption, e.g., to make recording  
1146 simpler, and the 'reporting' effect, whereby survey participants misreport what they  
1147 actually eat. This predominantly leads to under-reporting. There is evidence that  
1148 under-reporting is selective; fatty, sugary, and snack foods, and alcohol are more likely  
1149 to be under-reported than are other foods, such as fruit and vegetables (DH and FSA,  
1150 2012). Foods eaten outside the home may also be subject to more under-reporting,  
1151 particularly in surveys like NDNS that use a record-based methodology.

1152 Low response rates can lead to biased data sets, as some population sub-groups may  
1153 be under-represented. The age of the dietary survey data also affects the level of  
1154 uncertainty around the estimates, as consumption patterns change over time.

1155 The precision of exposure estimates is affected by the length of dietary data collection  
1156 as well as the methodology used for the collection of data. Older NDNS surveys  
1157 conducted for adults prior to the rolling program were carried out over 7-day periods  
1158 using a weighed diary method. The data collection period used was reduced to 4 days  
1159 when FSA moved towards a rolling program for collecting dietary information; this  
1160 reduction is associated with a potential for underestimation of the proportion of the  
1161 population who are consumers, which in turn could result in the overestimation of  
1162 consumption by consumers on a long-term basis.

1163 Since 2021, 'Intake 24' has been used for collecting NDNS data; it is a 24-hour recall  
1164 method. Participants are asked to complete 4 time-spaced recalls within 3-5 weeks,  
1165 using an online platform rather than the 4-day written diary entries. This shift in  
1166 approach was adopted as a basis for ameliorating the uncertainties linked to the  
1167 burden on respondents completing written diaries, thereby improving response rates  
1168 for the survey. However, the change from a written diary method to a 24-hour recall  
1169 approach is expected to result in uncertainties and challenges in interpreting trends  
1170 over time.

#### 1171 **Uncertainty from the chemical analysis of foods**

1172 Sources of analytical or occurrence data used can vary. Uncertainty in the analytical  
1173 measurement is routinely characterised by laboratory performance data. Food  
1174 analysis laboratories often use proficiency schemes such as FAPAS (Food Analysis  
1175 Performance Assessment Scheme) to demonstrate that they are able to measure an  
1176 analyte in a standardised reference material to acceptable standards. Sampling  
1177 uncertainty can arise from differences in levels of a chemical within and between  
1178 different batches of a foodstuff. The number of samples needed to represent the  
1179 population being tested is often an important consideration.

1180 Effects of food processing on the level or nature of chemicals in food is another source  
1181 of uncertainty. Whilst it is well-established that some contaminants are generated  
1182 during food processing and cooking (e.g., acrylamide, heterocyclic amines,  
1183 ethylcarbamate), there is currently no clear picture of the factors that influence whether  
1184 processes such as cooking will change the level or nature of other chemicals of interest  
1185 in food. Chemical analysis of cooked food is sometimes problematic, and acceptable  
1186 validated methods may not exist for foods in this state. Analysing cooked food also  
1187 may not meet other requirements of food chemical surveys, such as the assessment  
1188 of compliance with legislative levels (MRLs, CXLs, etc.) at the point of sale to the  
1189 consumer.

1190 For HSE's consumer risk assessment for pesticide residues, potential residues in  
1191 processed foods and the impact on consumer intakes is an area of uncertainty,  
1192 particularly where data (either processing data or consumption data) are limited. HSE  
1193 currently undertakes the majority of risk assessment based on residues in the RAC;  
1194 however, for some foodstuffs, these are never consumed as the RAC, and are only  
1195 consumed following some form of processing. As such, it can be useful to have

1196 additional information on the nature and magnitude of residue in a processed  
1197 commodity.

1198 There are specific data requirements which may need to be addressed, either for the  
1199 approval of a pesticide active substance or authorisation of a PPP, which are intended  
1200 to provide information on the nature and magnitude of a pesticide and/or its  
1201 metabolites and to allow derivation of processing factors (Pfs). Pfs can be used to  
1202 refine the consumer risk assessment, or to make an estimation of the level of pesticide  
1203 in the RAC, based on the measured amount of a chemical in a processed food.  
1204 Representative procedures of pasteurisation, baking, boiling, brewing, and sterilisation  
1205 can be used to indicate the nature of the residue that is expected in a processed  
1206 commodity.

1207 Even where data are available, there can still be uncertainty; Pfs are active substance  
1208 specific and both nature and magnitude studies will not cover all scenarios.  
1209 Sometimes, despite data being available, they cannot always be used by HSE, as the  
1210 current UK chronic risk assessment model does not contain consumption data for all  
1211 types of processed commodity, or the data may be based on only a small number of  
1212 consumers, and as such could be unreliable to represent a wider population.  
1213 Therefore, HSE tend to use consumption data for the RAC and apply a processing  
1214 factor.

#### 1215 **Uncertainty from the methodology used to calculate the exposure estimate**

1216 Within the general framework of chemical risk assessment, a challenging step in  
1217 dietary exposure assessment is the handling of concentration data reported to be  
1218 below the LOD. These data are known as non-detects and the resulting distribution of  
1219 occurrence values is left-censored. The difficulties associated with handling left-  
1220 censored data were recognised by EFSA (EFSA, 2010). EFSA has so far treated left-  
1221 censored data with widely used substitution methods, which are also used by the UK  
1222 Government Departments. The appropriateness of this approach has a natural  
1223 limitation in the computation of percentiles and in the application of statistical  
1224 techniques. EFSA considered the accuracy of the methods currently used and  
1225 proposed recommendations for more advanced alternative statistical approaches  
1226 (EFSA, 2010).

1227 In some estimates of exposure, a single assumed bodyweight is used, e.g., 60 kg.  
1228 This introduces a large source of uncertainty, although erring on the precautionary  
1229 side if actual body weights are higher. However, where consumption data are derived  
1230 from dietary surveillance, the individuals' measured bodyweight can be used in the  
1231 exposure assessment.

1232 Uncertainty introduced by brand loyalty is more difficult to reduce, except where  
1233 reliable market share data are available; these can potentially be used to augment  
1234 probabilistic models.

1235 The choice of model, the underlying data, and assumptions made about missing or  
1236 incomplete data all contribute to uncertainty. As these factors rely on expert  
1237 judgement, the experience and subjectivity of the individual conducting the  
1238 assessment can also affect uncertainty in the exposure estimate, although this

1239 uncertainty may be reduced by having a peer-review process (either formal or  
1240 informal) in place.

1241 Modelling exposure to food chemicals can lead to predictions that involve more  
1242 uncertainty than assessments based on direct measurement, e.g., using biomarkers.  
1243 However, reliable biomarkers are not available for all food chemicals of interest and  
1244 their use tends to be expensive. Where direct measurement is used, it can provide a  
1245 valuable way of validating exposure models.

1246 Before action can be taken to reduce the effects of these sources of uncertainty, they  
1247 need first to be quantified and then prioritised. This is required to ensure that resources  
1248 are directed at reducing relatively large sources of uncertainty before lesser sources  
1249 are tackled.

1250 ***Consideration of a possible common approach in the future***

1251 At present, each organisation conducts chronic risk assessments mostly  
1252 independently, using differing methodologies. These different approaches have  
1253 evolved based on the legislative data requirements applicable to the chemical of  
1254 interest, and for historic reasons within each department. However, each organisation  
1255 has a shared common goal, to be protective of consumers.

1256 As discussed in earlier sections, each organisation conducts risk assessment at  
1257 different levels of the tiered approach, outlined in Figure 1, to suit the needs of the  
1258 legislative requirements for that area. The level of the tiered approach, at which a risk  
1259 assessment is conducted, is dependent on several factors, including but not limited to,  
1260 the reason for the risk assessment being undertaken (hazard/risk potential), the  
1261 regulatory requirements and associated guidance, the level of protection required, and  
1262 the consumption or occurrence data available to each organisation.

1263 As an example, HSE currently conducts risk assessment at Tier 2 for the purpose of  
1264 active substance approval, MRL setting, and product authorisation assessments for  
1265 pesticides. This works within the regulatory framework for pesticides where model  
1266 diets based on NDNS/DNSIYC survey data are available and measured levels of  
1267 residues in a food item, based on residues field trials, must be submitted by  
1268 stakeholders.

1269 Additional steps up the 'tiers' to refine the risk assessment are not routinely undertaken  
1270 for pesticides. The risk assessment work undertaken as part of the residues monitoring  
1271 programme, could be considered to be at Tier 3, as monitoring data are used to  
1272 provide a more 'real world' estimate of exposure, based on measured residue levels  
1273 found in the food available on the market. In addition, for some food commodities,  
1274 more refined consumption data or calculation parameters (e.g., variability factors (VFs)  
1275 or processing factors (Pfs), etc.) are considered.

1276 For FSA, most assessments are simple conservative assessments, where no concern  
1277 is identified; however, additional steps up the tiers can be taken to refine the risk  
1278 assessment via complex deterministic assessments using the Creme Global software.

1279 For VMD, assessment of chronic dietary exposure is dealt with exclusively in  
1280 establishing MRLs, using a standard food basket and the TMDI approach. This

1281 approach generally fits somewhere between Tiers 1 and 2 of the exposure  
1282 characterisation process, as presented in Figure 1.

1283 As we move towards the future, it is relevant to consider if or how we can work to  
1284 develop common approaches for chronic risk assessment across the organisations,  
1285 to provide consistency and transparency in the process; this consideration forms one  
1286 of the purposes of this working group and report.

1287 Some key areas have been identified for further discussion:

- 1288 • The use of one shared food consumption database which can be utilised by all  
1289 organisations.
- 1290 • The use of the same consumer groups within the risk assessment (i.e., infant,  
1291 toddler, adult groups etc).
- 1292 • The potential to have a shared model capable of performing chronic exposure  
1293 assessment calculations suitable for all organisations.
- 1294 • A shared guidance on how chronic intake assessments are conducted.
- 1295 • The use of the same active substance endpoints (e.g., toxicological reference  
1296 values, ADIs, MRLs, and residue definitions).

1297 The latter will be discussed in the next section, where multiple use substances are  
1298 considered.

### 1299 **Consumption data**

1300 Currently, the consumption data used by each organisation differs in several aspects,  
1301 including but not limited to the age of the data, format (food basket/food as  
1302 consumed/RAC) and range of commodities considered.

1303 FSA currently holds the most up to date consumption data for UK consumers, based  
1304 on the latest NDNS/DNSIYC survey data and recipes database. These data cannot  
1305 automatically be used by VMD and HSE, due to the format in which the data are held  
1306 within the Creme software. The Creme software holds consumption data for foods  
1307 directly consumed by individuals, whereas the VMD and HSE need data for the RAC.  
1308 Recipes and reverse yield factors need to be applied, which is a complex process.  
1309 However, the development of a tool by which each organisation could access and use  
1310 recent dietary survey data originating from one source could be a project to investigate  
1311 further.

### 1312 **Consumer groups**

1313 The consumer groups currently used by each organisation differ. These differences  
1314 are built into the chronic risk assessment models used by each organisation.

1315 VMD currently use a standard food basket approach, representing the (conservatively  
1316 estimated) consumption of a 60 kg adult, which is the only age group considered.

1317 HSE conduct chronic risk assessment for 10 separate consumer groups, with specified  
1318 age ranges and mean bodyweights.

1319 FSA have survey data for participants ranging from 4 months to 95 years of age and  
1320 have flexibility in how critical groups might be considered.

1321 If a project were to be undertaken to move towards a common approach for chronic  
1322 risk assessment, where each organisation utilises consumption data from one source,

1323 it would make sense to consider the implications of using the same or similar ranges  
1324 for the consumer groups considered in the risk assessment.

### 1325 **Chronic risk assessment model**

1326 There are significant barriers to having the same chronic risk assessment model  
1327 across organisations, including the current differences in consumption data, consumer  
1328 groups, calculation methods, and legislative need of each organisation.

1329 Discussion has taken place regarding the use of shared consumption data and the  
1330 same consumer groups; a natural progression from this would be to consider the  
1331 opportunity to develop a complex model, capable of performing chronic risk  
1332 assessment estimations utilising the different calculation methods used by each  
1333 organisation. This would be a highly aspirational concept and would require significant  
1334 resource to develop and validate a model that would have the capability to allow both  
1335 simple and complex modelling (either deterministic or probabilistic) which would suit  
1336 the needs of each organisation.

### 1337 **Shared guidance**

1338 As discussed in Section 1, risk assessment is undertaken at differing levels of cost  
1339 and complexity, depending on the available data and regulatory need. Chronic risk  
1340 assessments are unlikely to proceed through the tiers if it can be concluded at an early  
1341 tier that there is no significant risk to consumers, or reasonable risk management  
1342 action can be taken to mitigate any risks identified.

1343 A project looking into the development of a shared guidance document, which can be  
1344 utilised by each organisation, focusing on the tiered approach outlined in Figure 1,  
1345 could be a worthwhile project to consider in working towards a common approach. The  
1346 guidance document could discuss scenarios of when or how it would be appropriate  
1347 to either continue with increasing refinement of the risk assessment, or whether risk  
1348 management options would be more appropriate.

1349 Any project looking into the development of such guidance would need to consider  
1350 how the specific legislation for each organisation could be accommodated and have  
1351 scope for case-by-case deviation from the guidance where this could be justified (or  
1352 there is industry need).

### 1353 **Possibility of a combined approach for multiple use substances**

1354 Some chemicals considered by FSA, HSE and VMD have multiple uses, e.g., iodine,  
1355 which has uses in biocides, VMPs, and food and feed additives, or copper, which has  
1356 uses in pesticides, VMPs, and food supplements.

1357 At present, although there is an awareness of these substances and some aspects of  
1358 joined up working do take place, the different organisations do not regularly work  
1359 together on the chronic risk assessments for these substances, unless there is a  
1360 specific concern identified. A brief discussion around the current combined  
1361 approaches for specific scenarios is given here, along with discussion around potential  
1362 changes which could be implemented for the future.

### 1363 **Current combined approaches**

1364 **Pesticides/veterinary medicines**

1365 HSE and VMD hold regular liaison meetings which provide an opportunity to discuss  
1366 new and upcoming guidance documents, any challenges facing each organisation  
1367 (e.g., regarding legislation) or 'hot topics' within risk assessment which could be  
1368 relevant to both organisations.

1369 Historically, MRLs for POAO for dual pesticide/veterinary medicine active substances  
1370 have been set at different levels under the different legislations for pesticide residues  
1371 and VMPs. As outlined below, steps to resolve this issue have already been  
1372 implemented.

1373 HSE and VMD share relevant information about current and future assessments of  
1374 active substances which could have dual pesticide/VMP uses. Sharing this information  
1375 at an early stage allows any concerns with regards consumer exposure and MRL  
1376 setting to be considered and, if required, discussion around appropriate endpoints can  
1377 take place.

1378 **Vitamins/food and feed supplements and biocides**

1379 Consumer exposure assessments for vitamins/supplements and biocides can overlap  
1380 between VMD, FSA and HSE. These are all complex areas and risk assessments are  
1381 undertaken by different organisations for different reasons, led by the circumstances,  
1382 resulting from the legislative requirements for each organisation.

1383 Biocides cover 22 diverse product types and most authorisations do not lead to  
1384 residues in food or feed. However, the use patterns of product types 3, 4, 5, 18 and  
1385 19 cover disinfectants used for veterinary hygiene, for the disinfection of food and feed  
1386 areas, for the disinfection of drinking water, and products used for the control of  
1387 arthropods. All of these can include uses that may lead to residues in food and feed.  
1388 Furthermore, the use patterns of these can be complex and hence require different  
1389 approaches to the consumer exposure, including first tier theoretical calculations.

1390 Despite the purpose of risk assessment for each scenario being different, there are  
1391 opportunities to consider a combined approach using agreed active substance specific  
1392 endpoints (e.g., toxicological reference values (TRVs), ADIs) within the risk  
1393 assessment. Furthermore, the three organisations will need to work together, as there  
1394 is no single regulation that covers setting MRLs for biocides. MRLs for biocides will be  
1395 established under different legislation depending on the nature of the active  
1396 substance:

- 1397 a) MRLs for biocides that are used in animal husbandry should be set under  
1398 veterinary medicines legislation.
- 1399 b) MRLs for biocides that are, or have been, plant protection products should be  
1400 set under the MRL regulation for pesticides.
- 1401 c) Biocides that may migrate into food/feed from treated packaging should be set  
1402 under the food contact materials legislation.
- 1403 d) MRLs for biocides that do not fall under the three criteria above, should be set  
1404 under the contaminants legislation.

1405 At the time of writing, no MRLs have been set for biocides in GB (or the EU). However,  
1406 it is clear, based on the range of different biocides, the complex use patterns, and the

1407 different legislation that may be used to set MRLs, that HSE, FSA and VMD will need  
1408 to consult together on the risk assessments and the setting of MRLs for biocides.

1409 Mechanisms are already in place for discussion between HSE/FSA and HSE/VMD for  
1410 biocides, with HSE having consulted with FSA on active substance dossiers and  
1411 products when required.

1412 This is an area in which we would continue to encourage the organisations to work  
1413 together where there are common sources of exposure, to ensure that endpoints used  
1414 in the assessment are aligned, where appropriate, and to note these as examples for  
1415 reference in future assessments.

1416 It should be noted that the process of aligning endpoints may not be straightforward,  
1417 and could take time to address, due to the legislation under which they have been set.  
1418 It would be expected that ADIs, Acute Reference Doses (ARfDs), and (marker) residue  
1419 definitions could be the same; however, should any of these need to be changed under  
1420 any of the regulatory regimes, a formal assessment would be required; new endpoints  
1421 cannot just be used in an assessment, they would have to be formally adopted. There  
1422 is further discussion of TRVs below.

#### 1423 **Looking to improve combined approaches**

1424 In each of the above scenarios, it is apparent that steps are being taken to start  
1425 working on combined approaches for multiple use substances, but this is without any  
1426 specific guidance and is often conducted on an *ad hoc* basis. It is apparent that a big  
1427 step forward in considering multiple use substances would be the consistent and  
1428 transparent use of agreed active substance hazard endpoints across all organisations.

#### 1429 **Toxicological reference values**

1430 In the context of this document, for the purpose of chronic risk assessment for multiple  
1431 use substances, the collective term toxicological reference value (TRV) is being used  
1432 to refer to ADIs, upper tolerance limits (UTLs), TTCs or other TRVs relevant to the  
1433 nature or use of the chemical.

1434 At present, although some substances have multiple uses, the TRV applicable for that  
1435 substance can differ between the regulatory areas. This results in the chronic risk  
1436 assessment for different organisations being conducted against different endpoints.  
1437 This makes it difficult to compare results between organisations and adds a layer of  
1438 complexity for anyone trying to understand the exposure assessment.

1439 A project which investigates aligning and agreeing a set of TRVs, which could be  
1440 stored within a central database for use in consumer risk assessment by all  
1441 organisations, could be a valuable step in ensuring consistency of assessment. It  
1442 would also provide transparency on the risk assessment for applicants, or others, who  
1443 are attempting to submit consumer risk assessments as part of regulatory dossiers.

1444 A project looking to align and develop a database for TRVs would need to consider  
1445 the legislative requirements, i.e., any new TRV would need to be assessed and  
1446 endorsed under the different regulatory regimes. Establishing new TRVs may take  
1447 time to coordinate between the agencies, and a move to change endpoints may not  
1448 be considered a priority.

1449 Additionally, for TRVs to be harmonised, it may be necessary to consider whether the  
1450 core data requirements of the organisations involved would require alignment so as to  
1451 enable TRVs to be established based on the same data, and whether such alignment  
1452 would be possible.

1453 It would need to be considered whether the above points would need to be resolved  
1454 ahead of a project to develop a database of agreed TRVs, i.e., would it be preferable  
1455 to have TRVs aligned before a shared database was developed, or is the alignment  
1456 of TRVs an issue that could be resolved over time and hence mechanisms could be  
1457 put in place to ensure when delivering decisions, dual uses are taken note of, and  
1458 ensure there is agreement on common TRVs.

#### 1459 **MRLs and residue definitions/marker residues**

1460 Alignment of MRLs (in animal produce) for dual use VMP and pesticide active  
1461 substances would ensure that there is clarity over the applicable MRL, for compliance  
1462 and enforcement purposes, for that particular substance/commodity combination.

1463 Some steps in improving consistency in this area are already being undertaken for  
1464 MRLs for substances with dual pesticide/VMP uses. There has been a drive, both in  
1465 the UK and EU, to ensure that where this is the case, a consideration of consumer  
1466 intakes originating from both sources can be taken into account.

1467 Now that there is an independent regime for GB MRLs, HSE intend to take into account  
1468 any VMP MRLs within the consumer risk assessment for MRL setting of dual  
1469 pesticide/VMPs. VMD already take pesticide uses into account when setting MRLs for  
1470 VMPs.

1471 It is important to note that for historic cases this approach was not taken and the MRLs  
1472 set for dual pesticide/VMPs may be different. The alignment of MRLs is likely to take  
1473 time.

1474 Currently, as an interim approach, if it is identified that either organisation (VMD/HSE)  
1475 is proposing to set new MRLs for products of animal origin, then a check should be  
1476 conducted to compare and contrast the current MRLs established under both  
1477 Regulations with the newly proposed ones; if no consumer risk issues are identified,  
1478 then the higher MRLs will be recommended, thus aligning the MRLs.

1479 As a longer-term approach, the various points discussed above would need to be  
1480 resolved, along with any legislative barriers. For this approach to work, it would be  
1481 necessary for the same residue definition for enforcement (marker residue) to be  
1482 established, or if this was not agreed, then a simple way of converting measured  
1483 residues to check compliance with MRLs would be required.

1484 At present, when VMD propose a new MRL for VMP use, a conservative approach is  
1485 used for the risk assessment whereby 55% of the ADI for the active substance is  
1486 reserved for the use of a substance as a pesticide. A suggestion to improve and refine  
1487 this process would be for HSE to provide VMD with specific consumer intake estimates  
1488 based on the authorised pesticide uses.

1489 Alternatively, if VMD proposes new MRLs for POAO for a dual pesticide/VMP active  
1490 substance, a process could be established where VMD provide, as a minimum, the  
1491 proposed MRLs, Highest Residues (HR) and STMRs (residue depletion study data) to

1492 HSE, to assess whether the new MRLs can be adopted using HSE's consumer risk  
1493 assessment approach. It should be noted that there is a mechanism currently in place  
1494 that allows HSE and FSA to comment on VMD MRL assessments at the initial  
1495 assessment stage, via attendance at the monthly Scientific Secretariat (SciSec)  
1496 meetings held at VMD.

1497 For either option, mechanisms would need to be put in place to allow this to occur  
1498 consistently, such as specific guidance documents, known contact points within each  
1499 organisation to allow the discussions to take place and, aspirationally, a shared  
1500 database of consumption data and agreed TRV endpoints. Even where agreed TRVs  
1501 are not in place, it would be possible for HSE to provide VMD with exposure  
1502 assessments for the pesticide uses, which could be added to the exposure scenarios  
1503 from the VMP uses and compared to an established TRV, and *vice versa*. A problem  
1504 which would make this more challenging would be where different residue definitions  
1505 (marker residues) are established across the two regimes, resulting in the exposure  
1506 assessment being conducted based on different approaches.

1507 As such, it would also be useful to have agreed residue definitions or marker  
1508 compounds, in much the same way as for TRVs and MRLs, to allow the appropriate  
1509 analytical determination of residues arising from the use of multiple use substances.  
1510 Having consistent residue definitions agreed across organisations would ensure that  
1511 where a risk assessment calculation has been carried out, the appropriate (total)  
1512 residue has been identified.

1513 Overall, it is considered that to improve consistency and transparency in the risk  
1514 assessment of multiple use substances, there is a clear need to agree on, and use,  
1515 the same active substance specific endpoints across organisations.

1516 For this to be possible, it firstly needs to be considered whether, legislatively, a position  
1517 can be agreed allowing the adoption of the same TRVs and residue definitions for  
1518 different regulatory regimes; for example, at this time it is not thought to be possible  
1519 that an assessment undertaken by VMD to establish residue definitions or TRVs could  
1520 be automatically adopted by HSE, and *vice versa*, due to the differences in the data  
1521 requirements for the different regimes. As such, it would need to be decided how an  
1522 active substance could be jointly reviewed and a common set of endpoints  
1523 established; this should account for the various timelines involved in active substance  
1524 assessment for each regime (e.g., active substance renewal assessments), which  
1525 may differ.

1526 If this can be resolved, further work would be required to develop an agreed database  
1527 of endpoints, and to develop guidance on how chronic risk assessment should be  
1528 undertaken involving collaborative working across organisations.

1529 ***Considerations regarding cumulative effects and aggregate exposure***

1530 Commission regulation (EU) No. 283/2013, which sets out the data requirements for  
1531 pesticide active substances<sup>5</sup> states:

---

<sup>5</sup> As retained EU law relevant to GB and amended by the appropriate statutory instrument (SI) [The Plant Protection Products \(Miscellaneous Amendments\) \(EU Exit\) Regulations 2019 \(legislation.gov.uk\)](https://www.legislation.gov.uk/uk/2019/1222)

1532 'Where relevant, the possible presence of pesticide residues arising from sources  
1533 other than current plant protection uses of active substances (for example use of active  
1534 substances resulting in common metabolites, use as biocide or veterinary drug), and  
1535 their aggregate exposure shall be taken into account. In addition, the cumulative  
1536 exposure to more than one active substance shall, where relevant, be considered.'

### 1537 **Aggregate exposures**

1538 Aggregate exposure and risk assessment is considered to be exposure to a single  
1539 chemical by multiple pathways and routes of exposure, e.g., from consumption of  
1540 chemicals in food or water in combination with residential or occupational exposure  
1541 routes.

1542 Aggregate exposure assessments are highly challenging. Other than setting aside a  
1543 proportion of the ADI when establishing MRLs in veterinary medicine for dual use  
1544 substances, the UK does not conduct aggregate exposure assessments for pesticides  
1545 or VMPs. This is not a requirement as, at present, there are no guidelines or suitably  
1546 validated models available to allow aggregate exposure assessments to be  
1547 conducted.

1548 Aggregate exposure assessments are an area of pesticide risk assessment which is  
1549 under regular review within the EU. A notable project in this regard is the EuroMix  
1550 project (Funded by EU Horizon 2020), which aimed to develop relevant methods and  
1551 tools for risk assessment for chemical mixtures, including from multiple sources  
1552 (Kennedy et al., 2019).

1553 At the current time, aggregate exposure assessments are not carried out routinely in  
1554 the EU, however some Member States have performed dietary mixture exposure  
1555 assessment using EuroMix data and models, and three case studies addressing  
1556 multiple exposure routes of bisphenols and pesticides, are planned to be published.<sup>6</sup>

1557 In the USA, the Environmental Protection Agency (EPA) does undertake some level  
1558 of aggregate exposure assessment within their pesticide regulatory regime. The US  
1559 EPA General Principles for Performing Aggregate Exposure and Risk Assessments  
1560 for Pesticides (EPA, 2021) highlights that 'All potential, relevant routes of exposure are  
1561 analysed within an aggregate exposure assessment. These include the oral, dermal  
1562 (absorption), and inhalation routes of exposure.' According to the general principles,  
1563 this is carried out using a combination of data, models, and reasonable judgements,  
1564 to represent each potentially exposed 'individual' in the population over time.

1565 FSA does on occasion conduct some level of aggregate exposure assessments, e.g.  
1566 combining exposures from food with water and with those from dust/soil (COT, 2016).  
1567 These aggregate exposure assessments are only considered on a case-by-case  
1568 basis, where required.

### 1569 **Cumulative exposures**

1570 Cumulative exposures, also referred to as combined exposures, refer to the potential  
1571 exposure effects from two or more chemicals that may have the same/similar or

---

<sup>6</sup> [The truth about our exposure to chemical cocktails and its impact on our health | EuroMix Project | Results in brief | H2020 | CORDIS | European Commission \(europa.eu\)](#)

1572 interlinked modes of action. Effects resulting from exposure to multiple chemicals is  
1573 sometimes termed the 'cocktail effect'.

1574 Cumulative risk assessment requires consideration of complex interacting sets of data  
1575 which cover toxicology, residues, and risk management issues; it represents another  
1576 challenging area of risk assessment. Methodologies and research activities developed  
1577 so far mainly focus on combined exposure to predefined groups of chemicals within a  
1578 specific regulatory domain (e.g., pesticides, biocides). These often do not cover  
1579 mixtures of chemicals across different regulatory domains/sectors, nor do they  
1580 account for all the chemicals humans may be potentially exposed to.

1581 A challenge to doing this, is that for groups of chemicals that have a strong evidence  
1582 base in terms of hazard and exposure data (e.g., pesticides), it is difficult to combine  
1583 the information with other risk assessment areas where less information or a more  
1584 pragmatic approach is recommended, such as the mixture assessment (or allocation)  
1585 factor (MAF).

1586 Within the UK and EU, there currently are no guidelines, or models, for cumulative  
1587 exposure assessment, either chronic or acute, to be routinely conducted across any  
1588 of the regulatory regimes. EFSA are working to develop new approaches and tools for  
1589 harmonising how risks to humans (and the environment) from combined exposure to  
1590 multiple chemicals can be assessed. EFSA's scientific committee published a  
1591 guidance document on methodologies for risk assessment of combined exposure to  
1592 multiple chemicals in 2019 (EFSA, 2019b).

1593 EFSA held an international workshop in October 2021 on the risk assessment of  
1594 chemical mixtures<sup>7</sup>, following which they finalised and published guidance on the  
1595 scientific criteria for grouping chemicals into assessment groups for risk assessments,  
1596 assuming dose addition (EFSA, 2021b).

1597 Chemicals are to be grouped based on a common mode of action (MoA) or Adverse  
1598 Outcome Pathway (AOP). In cases where the MoA or AOP is unknown, chemicals are  
1599 to be grouped based on a common adverse outcome, or if that is unknown, a common  
1600 target organ or system.

1601 In 2019, a Joint FAO/WHO Expert Consultation was held, which proposed an  
1602 approach to the risk assessment of combined exposure to multiple chemicals. This  
1603 approach is now being trialled for VMPs and pesticides by JECFA and JMPR (WHO,  
1604 2020b; FAO and WHO, 2020). As a pragmatic cut-off, it was proposed that if the  
1605 estimated dietary exposure for a substance is less than or equal to 10% of its HBGV  
1606 for all population groups assessed, it does not need to be considered in a risk  
1607 assessment of combined exposure. If exposure is greater than 10% of its HBGV, then  
1608 the need to include the substance in a risk assessment of combined exposure to  
1609 multiple chemicals should be considered.

1610 A weight of evidence approach should be used to determine whether there is evidence  
1611 for combined effects of the substance with other substances, taking into account  
1612 structural similarities, modes of action or adverse outcome pathways, and shared

---

<sup>7</sup> [EFSA International Workshop on Risk Assessment of Combined Exposure to Multiple Chemicals | EFSA \(europa.eu\)](https://www.efsa.europa.eu/en/efsajournal/doc/5422/attachment/68222)

1613 adverse effects. The default assumption should be dose addition, but the possibility of  
1614 synergistic interactions should be considered on a case-by-case basis. It is anticipated  
1615 that joint assessments of groups of pesticides and VMPs will be conducted in the future  
1616 if required.

1617 For pesticide product authorisation, HSE conducts a simple assessment of combined  
1618 chronic (and acute) exposure where a PPP contains two or more pesticides. The  
1619 assessment is limited and basic in nature, as it only considers combined exposure  
1620 where they are approved for use together in the same product; no consideration of  
1621 cumulative exposure from other scenarios (e.g., tank mixtures) is considered.

1622 Initially, the exposure assessment is carried out on a tier 1 assumption of combined  
1623 toxicity. Assumed combined toxicity saves resource (initially) and is conservative, and  
1624 therefore protective of consumers. It allows scope for refinement if there is an  
1625 indication of potential risk, by determining whether there are true AOPs common to  
1626 both chemicals which could result in combined/synergistic toxic effects. This requires  
1627 input from toxicologists. If there is an indication of risk based on a tier 1 assumption of  
1628 combined toxicity, and it is later confirmed that there are no common adverse effects,  
1629 then the cumulative risk assessment can be refined.

1630 Cumulative risk assessments are also considered as part of the PRiF monitoring  
1631 programme. A combined risk assessment is conducted for substances which are  
1632 known to belong to the same cumulative assessment groups (CAGs), such as  
1633 triazoles, or AChE inhibitors, where they are detected above the reporting limit within  
1634 the same sample. The approach to cumulative risk assessment is limited, as it is  
1635 considered on a single commodity basis. Due to the nature of the PRiF risk  
1636 assessments, generally only acute risk is considered in the cumulative assessment;  
1637 however, on a case-by-case basis, where two or more chemicals from the same CAG  
1638 are found in >50% of samples, combined chronic risk is also considered.

1639 Chronic risk from aggregate and cumulative exposure is an uncertainty at present.  
1640 This could be considered an area where future research could potentially seek to  
1641 develop methodologies to address these challenges in chronic risk assessment.

#### 1642 ***Less than lifetime approach***

1643 There has recently been a programme of work to harmonise the approaches of JMPR  
1644 and JECFA to chronic dietary exposure assessment (Arcella et al., 2019). The JMPR  
1645 model, which uses per capita estimates of food consumption, was considered to  
1646 estimate lifetime exposure, whereas the models used by JECFA, which consider  
1647 exposure separately for children and adults, and for mean and high-level consumers,  
1648 were considered to estimate less than lifetime exposures. A decision tree was created  
1649 in order that the appropriate dietary exposure assessment model could be used in risk  
1650 assessment, depending on the toxicological profile of the chemical.

1651 The approach currently taken by HSE for pesticides, and by FSA for contaminants,  
1652 would be considered a less than lifetime approach, as it assesses the exposures of  
1653 different population subgroups and high-level consumers and compares them to the  
1654 HBGV that has been established to be protective for long-term exposure. In contrast,  
1655 the current approach used by the VMD does not assess exposures for children, though  
1656 for adults, the model diet used aims to cover high level consumers.

1657 The Committee on Carcinogenicity of Chemicals in Food, Consumer Products and the  
1658 Environment (COC) has recently produced a set of principles on assessing risks from  
1659 less than lifetime exposure to carcinogens (COC, 2019), and the COT has also  
1660 produced a statement on assessing risks from less than lifetime exposure (COT,  
1661 2021). The COT preferred the term 'less than lifetime or variable exposure over a  
1662 lifetime', since for most food chemicals the exposure is not shorter than a lifetime and  
1663 then ceases, but rather the exposure is over a lifetime but varies over that lifetime,  
1664 being substantially higher for a certain portion of it.

1665 The COT statement recommends that less than lifetime exposures, or exposures in  
1666 the window of raised exposure, should initially be compared to a HBGV that has been  
1667 established to be protective for long-term exposure, which is consistent with the  
1668 approaches currently undertaken by HSE and FSA. However, if required, it  
1669 recommends approaches that may be taken to refine the risk assessment in cases  
1670 where exposure averaged over a time frame relevant to the basis upon which the  
1671 HBGV is established is less than the HBGV, but shorter-term exposure exceeds it.

1672 For chemicals without established HBGVs, margins of exposure (MOEs) may be  
1673 calculated. Similarly, calculating the MOE for the less than lifetime exposure or the  
1674 window of raised exposure, the COT principles, and the COC principles in the case of  
1675 non-genotoxic carcinogens, recommend considerations that may be applied in refining  
1676 the risk assessment if this initially calculated MOE is insufficiently large to conclude  
1677 there is no safety concern. For chemicals which are genotoxic and carcinogenic, the  
1678 MOE is also initially calculated based on the less than lifetime exposure or exposure  
1679 in the window of raised exposure, but there are specific considerations for these in the  
1680 COC principles (COC, 2019).

### 1681 ***Acute exposure***

1682 The focus of this report is on approaches to chronic dietary exposure assessment.  
1683 However, FSA and HSE also undertake acute dietary exposure assessments for  
1684 chemicals for which there is the potential for a single exposure to cause adverse  
1685 effects. In most cases this involves comparing the estimated exposures to established  
1686 acute reference doses (ARfDs), while in other cases margins of exposure may be  
1687 calculated to point of departure relevant to acute exposure in the absence of an  
1688 established ARfD. Acute dietary exposure assessments are commonly either  
1689 deterministic assessments, based on high percentiles of residue concentration and  
1690 high percentiles of consumption, or probabilistic modelling.

1691 VMD does not generally assess acute dietary exposures for VMPs, but this would  
1692 become of greater importance if a more refined, higher tier approach were to be taken  
1693 to chronic dietary exposure assessments, such as when considering the potential for  
1694 VMP residues to cause acute adverse effects in humans, e.g., following ingestion of  
1695 the injection site. Since the change by JECFA to the GECDE and GEADE approaches  
1696 to chronic and acute exposure assessments for VMP residues, respectively, JECFA  
1697 has begun to establish ARfDs for VMPs, and has published guidance on when it is  
1698 necessary to, and how, to establish ARfDs for VMPs (WHO, 2017).

1699 **4. Conclusions and recommendations for future work**

1700 ***Approaches to exposure assessments***

1701 FSA, HSE, and VMD have different remits under their respective legislation, and have  
1702 different expectations for their respective outputs. For example, VMD establishes  
1703 conservative MRLs for VMP active substances, which are protective of adult high-level  
1704 consumers of POAOs, but may not, on the face of it, be as protective for, e.g.,  
1705 toddlers/infants. These assessments are considered to be a low tier approach but are  
1706 not the final level of consumer protection; risk mitigation measures in the form of  
1707 product- and species- specific withdrawal periods are established when VMPs are  
1708 authorised. Withdrawal periods are defined as the time that elapses between the final  
1709 treatment of an animal, and the time when that animal can be slaughtered and enter  
1710 the human food chain, or commodities such as milk or eggs can be taken for human  
1711 consumption. This allows time for the animals' normal metabolic processes to break  
1712 down and eliminate the chemicals of concern before the consumer is exposed. In  
1713 practice, VMPs are not always given to the animals at a time when they are close to  
1714 slaughter, or are ready to start producing milk, and so there are multiple factors that  
1715 reduce the real-world exposure to VMPs. This approach is not possible for either HSE  
1716 or FSA, since withdrawal periods cannot be established for other types of  
1717 contaminants in the same way.

1718 For example, when animals consume pesticide residues as part of their feed, they  
1719 cannot be put on a withdrawal period, as it is unknown at the time of feeding what  
1720 contaminants are in their feed (and they still need to eat); as such, levels must be  
1721 controlled at an earlier stage in the process.

1722 Both HSE and FSA use lower tier approaches for screening purposes, and higher tier  
1723 approaches where more accurate calculations are required. This tiered approach  
1724 allows for management of resources and focusses on the higher-priority risks.

1725 For all agencies, the priority is the protection of consumers that may be exposed to  
1726 contaminants in their foods.

1727 Exposure assessments generally should take account of high-level consumers and all  
1728 subgroups of the population considered relevant from toxicological data that are used  
1729 to establish the HBGVs, e.g., infants, children, pregnant women, and older adults.

1730 No matter what approach is taken, it should be ensured that conservative assumptions  
1731 are made so that any potential dietary exposures are not underestimated. Where  
1732 higher tier approaches are used, it should still be ensured that these do not  
1733 underestimate high dietary exposures.

1734 ***Transparency of assessments***

1735 For any chemical risk assessment, the key uncertainties in the dietary exposure  
1736 assessment should be communicated as part of the risk assessment.

1737 ***Collaboration between agencies***

1738 Although each agency has different regulatory remits and different consumer  
1739 protection goals, there are areas where collaboration could take place. For example,  
1740 consideration should be given to using a common source of dietary consumption data,  
1741 and in the longer term, consideration should be given to conducting a single chronic

1742 dietary exposure assessment for chemicals with multiple uses (e.g., those used as  
1743 both a VMP and a pesticide), covering all sources of dietary exposure, where feasible.

1744 Since assessment groups for combined exposure may cross regulatory boundaries, it  
1745 is recommended that discussions be held between FSA, HSE and VMD on the  
1746 methodologies for combined chemical dietary exposure assessment for chronic  
1747 exposure. Cross-department/agency working may be required on combined risk  
1748 assessments.

1749 ***International considerations***

1750 In order to trade effectively with other nations and regulatory regions, the UK needs to  
1751 collaborate with international standard-setting authorities, such as CODEX, to  
1752 establish internationally recognised safe levels of contaminants in foods and feeds.  
1753 There is already extensive interaction with standard-setting committees, such as  
1754 JMPR and JECFA, from all three agencies. It may be appropriate in the future to move  
1755 towards using the same methodologies as these committees, so that a) we become  
1756 experts in said methodologies and can use that expertise to influence the  
1757 recommendations made, and b) make it more likely that UK standards harmonise with  
1758 international standards.

1759 ***Future work***

1760 The exposure assessment methodologies used in regulatory contexts should be  
1761 periodically reviewed for fitness for purpose and their uncertainties considered.

1762 There are already nascent collaborations between the Government departments and  
1763 agencies to consider the establishment of common HBGVs and MRLs, but this could  
1764 be progressed and be established as routine, and even go further and be established  
1765 in legislation and/or guidance.

1766 To have sufficient confidence in the consumption data available, progress on acquiring  
1767 comprehensive, regular, up-to-date consumption data is a priority, alongside the  
1768 establishment of a more comprehensive commodity list for HSE and review of  
1769 calculation approaches. In addition, there should be a central database to which all  
1770 UK regulators have access and thorough training on the use of. This should act to  
1771 reduce some of the uncertainties inherent in the exposure assessments.

1772 Further research is needed to develop methods to allow chronic risk from aggregate  
1773 and cumulative exposures to chemicals, or groups of chemicals of concern to be  
1774 assessed.

1775

1776

1777

1778 **Glossary**

1779 **ACP: Advisory Committee on Pesticides**

1780 ACP was the predecessor to the current Expert Committee on Pesticides.

1781 **ADI: Acceptable Daily Intake**

1782 An estimate of the amount of chemical that can be ingested daily over a lifetime  
1783 without an appreciable health risk to the consumer. It is applied to residues of  
1784 pesticides and veterinary drugs, as well as food additives, and is usually  
1785 expressed on body weight basis (mg/kg bw/day).

1786 **Aggregate exposure:**

1787 The combined exposure to a single chemical substance across multiple routes  
1788 (oral, inhalational, dermal) and pathways (food, drinking water) of exposure.

1789 **AOP: Adverse Outcome Pathway**

1790 A sequence of events, commencing with initial interactions of a stressor with a  
1791 biomolecule in a target cell or tissue (molecular initiating event), progressing  
1792 through a dependent series of intermediate events and culminating with an  
1793 adverse outcome.

1794 **ARfD:** Acute Reference Dose

1795 **BW:** Body weight

1796 **CAG:** Cumulative assessment groups

1797 **COC:** [Committee on Carcinogenicity of Chemicals in Food, Consumer Products, and](#)  
1798 [the Environment](#)

1799 **CODEX:** Established in 1963 by the Food and Agriculture Organization of the United  
1800 Nations (FAO) and World Health Organization (WHO), the Codex Alimentarius  
1801 Commission (CAC) is the body responsible for all matters regarding the  
1802 implementation of the Joint FAO/WHO Food Standards Programme.

1803 **COT:** [Committee on Toxicity of Chemicals in Food, Consumer Products, and the](#)  
1804 [Environment](#)

1805 **Cumulative exposure:**

1806 Cumulative exposures, also referred to as combined exposures, refer to the  
1807 potential exposure effects from two or more chemicals that may have the  
1808 same/similar or interlinked modes of action.

1809 **CVMP:** [Committee for Medicinal Products for Veterinary Use; A committee of the](#)  
1810 [European Medicines Agency \(EMA\)](#)

1811 **CXL:** CODEX limit

1812 **DH:** Department of Health

1813 The Department of health (DH) has since become the Department of Health  
1814 and Social Care (DHSC), Jan 2018.

1815 **DNSIYC:** Diet and Nutrition Survey for Infants and Young Children

1816 The DNSIYC survey was commissioned by the Department of Health (DH) and  
1817 the Food Standards Agency (FSA) in 2011 to provide detailed information on  
1818 the food consumption, nutrient intakes and nutritional status of infants and  
1819 young children aged 4 up to 18 months living in private households in the UK.

1820 **Dual (or multiple) use substance:**

1821 A substance that could be used in multiple regulatory areas, e.g., some  
1822 pesticides can also be used as veterinary medicines.

1823 **Deterministic:**

1824 if something is deterministic, you have all the data necessary to predict  
1825 (determine) the outcome with 100% certainty. The process of calculating the  
1826 output is called a deterministic process or procedure.

1827 **ECP:** [Expert Committee on Pesticides](#)

1828 **EDI:** Estimated Dietary Intake

1829 The estimated amount of a substance ingested by a person as part of their diet  
1830 (via food, water, beverages, and supplements)

1831 **EFS:** Expenditure and Food Survey

1832 **EFSA:** [European Food Safety Authority](#)

1833 **EPA:** Environmental Protection Agency

1834 **EU:** European Union

1835 **EUCP:** European union coordinated programme

1836 **FAO:** [Food and Agriculture Organization](#) of the United Nations

1837 **FAPAS:** Food Analysis Performance Assessment Scheme

1838 **FSA:** [UK Food Standards Agency](#)

1839 **GAP:** Good agricultural practice

1840 **GEADE:** Global Estimate of Acute Dietary Exposure

1841 **GECDE:** Global Estimate of Chronic Dietary Exposure

1842 **GEMs:** Global Environmental Monitoring and assessment programme

1843 **HBGV:** Health Based Guidance Value

1844 A numerical value derived by dividing a point of departure, e.g., benchmark  
1845 dose lower confidence limit, BMDL<sub>10</sub>, by a composite uncertainty factor, to  
1846 determine the levels of a substance that can be ingested over a defined period  
1847 without an appreciable risk to health.

1848 **HR:** Highest Residue

1849 The highest residue determined in a study conducted in accordance with the  
1850 critical dose regimen or application procedure.

1851 **HSE:** [Health and Safety Executive](#)

- 1852 **IEDI:** International Estimated Dietary Intakes
- 1853 **JECFA:** [Joint FAO/WHO Expert Committee on Food Additives](#)
- 1854 **JMPR:** [Joint FAO/WHO Meeting on Pesticide Residues](#)
- 1855 **LB:** Lower bound
- 1856           Where the concentration is <LOD and/or <LOQ, then the output is assumed to  
1857           be 0
- 1858 **LCF:** Living Costs and Food Survey
- 1859 **LD<sub>50</sub>:** Median lethal dose
- 1860           A dose at which 50% of exposed subjects are expected to die.
- 1861 **LOD:** Limit of Detection
- 1862           The minimum concentration of an analyte in a sample that can be quantitatively  
1863           detected, but cannot be quantitatively determined, under a pre-established set  
1864           of analytical conditions
- 1865 **LOQ:** Limit of Quantification
- 1866           The minimum concentration of a component that can be determined  
1867           quantitatively with acceptable accuracy and consistency.
- 1868 **MAF:** Mixture assessment factor
- 1869 **MC:** Mean consumption
- 1870 **Mean:**
- 1871           Suppose we have observed  $n$  values  $x_1, x_2, \dots, x_n$ .
- 1872           The mean value of the  $n$  observations is calculated as:
- $$\bar{x} = \frac{\sum_{i=1}^n x_i}{n} = \frac{x_1 + x_2 + \dots + x_n}{n}$$
- 1873
- 1874 **Median:**
- 1875           The median is the middle number in a sorted, ascending, or descending list of  
1876           numbers and can be more descriptive of that data set than the mean. It is the  
1877           point above and below which half (50%) the observed data falls, and so  
1878           represents the midpoint of the data.
- 1879 **MoA:** Mode of Action
- 1880           A biologically plausible sequence of key events in an organism leading to an  
1881           observed effect, commonly supported by robust experimental observations and  
1882           mechanistic data
- 1883 **MOE:** Margin of exposure
- 1884 **MRC HNR:** Medical Research Council's Human Nutrition Research Unit
- 1885 **MRL (PPPs):** Maximum Residue Level

- 1886 An MRL is the maximum concentration of a pesticide residue in or on food or  
1887 feed that is legally tolerated when a plant protection product (PPP) is applied  
1888 correctly (following good agricultural practice). MRLs are regulated in GB and  
1889 the EU under Regulation (EC) 396/2005. They are a trading limit, not a safety  
1890 limit.
- 1891 **MRL (VMPs):** Maximum Residue Limit
- 1892 The maximum allowed concentration of residue in a food product obtained from  
1893 an animal that has received a veterinary medicine or that has been exposed to  
1894 a biocidal product for use in animal husbandry.
- 1895 **NDNS:** National Diet and Nutrition Survey programme
- 1896 The NDNS rolling programme is a continuous, cross-sectional survey designed  
1897 to collect detailed, quantitative information on the food consumption, nutrient  
1898 intake and nutritional status of the general population aged 1.5 years and over  
1899 living in private households in the UK.
- 1900 **NEDI:** National Estimates of Dietary Intakes
- 1901 **97.5<sup>th</sup> percentile:**
- 1902 The percentile is the value of a variable below which a certain percentage of  
1903 observations fall. The 97.5<sup>th</sup> percentile is the value of exposure below which  
1904 97.5% of the population falls. If n=100 people and the values are sorted in  
1905 ascending order, the 97.5<sup>th</sup> percentile falls between the 97<sup>th</sup> and 98<sup>th</sup> person.
- 1906 **OECD:** [Organisation for Economic Cooperation and Development](#)
- 1907 **PFs:** Processing factors
- 1908 **POAO:** Products of animal origin
- 1909 **PPP:** Plant Protection Products
- 1910 **PRiF:** [Expert Committee on Pesticide Residues in Food](#)
- 1911 **PRIMo:** Pesticide Residue Intake Model
- 1912 **Probabilistic:**
- 1913 Probabilistic actions, methods, or arguments are based on the idea that you  
1914 cannot be certain about results or future events, but you can judge whether or  
1915 not they are likely, and act on the basis of this judgment.
- 1916 **PSD:** Pesticide Safety Directorate
- 1917 PSD was the predecessor to the current Chemicals Regulatory Division (CRD).
- 1918 **RAC:** Raw Agricultural Commodity
- 1919 **RD-Enf:** Residue definition for enforcement
- 1920 **RD-RA:** Residue definition for risk assessment
- 1921 **RL:** Reporting limit

1922            Used in the PRiF monitoring program. Used to describe the limit of  
1923            determination that is the lowest levels our tests are set to measure. The RL can  
1924            vary for different analytes or commodities.

1925    **STMR:** Supervised Trials Median Residues

1926    **STMR-P:** Supervised Trials Median Residues – processed commodities

1927    **TDS:** Total Diet Studies

1928    **TMDI:** Theoretical Maximum Daily Intake

1929    **TRV:** Toxicological reference value

1930    **TTC:** Threshold of Toxicological Concern

1931    **UB:** Upper bound

1932            Where the concentration is <LOD then the output is assumed to be equal to the  
1933            LOD and if the concentration is between the LOD and the LOQ, then the output  
1934            is assumed to be equal to the LOQ.

1935    **UK:** United Kingdom

1936    **US:** United States

1937    **UTL:** Upper Tolerance Limits

1938    **VFs:** Variability factors

1939    **VMD:** [Veterinary Medicines Directorate](#)

1940    **VMP:** Veterinary Medicinal Product

1941    **WCCE:** worst-case consumer exposure

1942    **WHO:** [World Health Organization](#)

1943    **WIGRAMP:** Working Group on Risk Assessment of Mixtures of Pesticides and Similar  
1944    Substances

1945

## ANNEX 1 – Summary of current approaches to chronic dietary exposure assessment for pesticides and veterinary medicines

|                         |  |                  |   |
|-------------------------|--|------------------|---|
| Area of concern         | Pesticides   |                  |   |
| Organisation            | HSE  |                  | JMPR  |
| Uses                    | <ul style="list-style-type: none"> <li>Assessment of potential exposure at active substance approval or product authorisation, based on median residue values (STMR) from residue trial data for the proposed crop uses only.</li> <li>Assessment of potential exposure for MRL setting and review. This will consider all authorised pesticide uses of the active substance (note STMR values may not be available for all uses if an MRL review has not yet taken place).</li> <li>Assessment of exposure based on monitoring data. Note this currently occurs on a commodity basis (if &gt;50% of the samples for a particular commodity have determinable residues of the same active substance).</li> </ul> |                  | <p>Assessment of specific potential public health concern.</p> <p>Periodic review of pesticide active substance data and MRLs. Assessment of potential exposure for new MRL setting or MRL review.</p> <p>The JMPR can only evaluate data relating to uses that are already registered in at least one country.</p> |
| Model/ Calculation tool | UK Chronic model   | EFSA PRIMO v 3.1 | <p><a href="#">Template for the evaluation of chronic exposure(IEDI) xlsx, 1.55Mb</a></p> <p>Version 04, 2019</p>   |

|                          |  |  |  |
|--------------------------|--|--|--|
| <b>Area of concern</b>   | <b>Pesticides</b>  |  |  |
| <b>Organisation</b>      | <b>HSE</b>   |  | <b>JMPR</b>  |
| Origin of substance data | Pre-registration supervised residue trial field data derived in accordance with Reg EC 1107/2009.<br><br>OR<br><br>Monitoring data derived as part of the PRiF programme |  | Supervised residue trial field data.   |
| Assumptions              | IEDI < ADI is acceptable<br><br>Chronic exposure is considered per active substance.   | IEDI < ADI is acceptable<br><br>Chronic exposure is considered per active substance.                 | IEDI < ADI is acceptable<br><br>Chronic exposure is considered per active substance.<br><br>Percentages above 100% not necessarily interpreted as giving rise to a health concern due to the conservative assumptions of assessments. Where the ADI is exceeded, JMPR indicates parts of the risk assessment leaving room for refinement. At the National level, potential refinements include taking into account more detailed information on food consumption, monitoring and surveillance data, total diet or reliable data on the percentage of crop treated and percentage of crop imported. |
| Consumption data         | NDNS and DNSIYC.   | From a variety of EU member states and WHO. Calculation back to RAC performed at member state level. | WHO cluster diets based on Food Balance sheets and Codex commodity codes   |

|                         |  |  |   |
|-------------------------|--|--|---|
| <b>Area of concern</b>  | <b>Pesticides</b>  |  |   |
| <b>Organisation</b>     | <b>HSE</b>   | <b>JMPR</b>  |   |
|                         | Based on 7 day food diaries (4 days toddler and elderly).  |  |   |
| <b>Approach</b>         | <p>Rees- day approach</p> $\sum_{x=i}^j \frac{STMR_i \times P97.5consumption_i}{BW} + \sum_{x=k}^n \frac{STMR_k \times MC_k}{BW}$ <p>i, j: two raw agricultural products leading to the highest intake;<br/>k, l, m, ...n: remaining raw agricultural commodities consumed</p> <p>P97.5consumption= 97.5<sup>th</sup> percentile consumption of RAC in kg/day based on mean daily intakes of consumers only.</p> <p>MC = mean consumption of RAC in kg/day derived from mean daily intakes of whole population (consumers and non consumers).</p> <p>STMR= Supervised Trial Median Residue. Residue value derived from pre-registration data. Note for monitoring data, median residue of monitoring values is used.</p> | $\sum_{x=i}^n \frac{STMR_i \times MC_i}{BW}$ <p>i, j, k, ...n: individual raw agricultural products</p> <p>Calculation of mean consumption is not standardised across the consumption data used.</p> <p>Also includes Rees- day approach but not relied upon for regulatory decision making (by GB or EU).</p> | $IEDI = \sum (STMR_i \times F_i)$ <p>Fi:GEMS/Food regional consumption of food commodity i</p> <p>Based on mean per capita intake from food balance (e.g., production minus exports plus imports).</p> <p>STMRi (or STMR-Pi): STMR (or STMR-P) for food commodity i</p> <p>When the pesticide is also used as veterinary drug and MRLs were established for animal commodities, the veterinary drug residues should also be taken into account in the IEDI calculation.</p> |
| <b>Consumer groups/</b> | Adult, infant, toddler, 4-6 years, 7-10 years, 11-14 years, 15-18 years, vegetarian, elderly (own home), elderly (residential)   | Encompasses a variety of sub groups and survey approaches (e.g., 7 day   | No consumer groups. Seventeen cluster diet groupings covering regions with similar dietary patterns.  |

|                        |  |  |   |
|------------------------|--|--|---|
| <b>Area of concern</b> | <b>Pesticides</b>  |  |   |
| <b>Organisation</b>    | <b>HSE</b>   |  | <b>JMPR</b>   |
| critical groups        | Note requirement for consideration of vulnerable groups pregnant women, infants and children.  | diets, WHO cluster diets, Swedish 90 <sup>th</sup> centile consumption).<br><br><a href="#">Use of EFSA Pesticide Residue Intake Model (EFSA PRIMo revision 3) (wiley.com)</a>   |   |
| Body weights           | Adult (76 kg), infant (8.7 kg), toddler (14.5 kg), 4-6 years (20.5 kg), 7-10 years (30.9 kg), 11-14 years (48 kg), 15-18 years (63.8 kg), vegetarian (66.7 kg), elderly-own home (70.8 kg) , elderly- residential (61.6 kg)  | Variety of standard bodyweights used depending on consumption data source.   | All 60 kg except for G09 diet 55kg.   |
| Refinement             | Processing data can be used to refine the assessment. However, refinements only possible if a commodity is predominantly consumed processed or sufficient consumption data is available to capture the combined consumption via RAC and any processed commodities. | Processing data can be used to refine the assessment. However, refinements only possible if a commodity is predominantly consumed processed or sufficient consumption data is available to capture the combined consumption via RAC and any processed commodities. | Processing data can be used to refine the assessment. See also assumptions above. |

|                         |  |  |   |
|-------------------------|--|--|---|
| <b>Area of concern</b>  | <b>Pesticides</b>  |  |   |
| <b>Organisation</b>     | <b>HSE</b>   |  | <b>JMPR</b>   |
| LOQ values <sup>1</sup> | Currently considered for risk assessment at the LOQ.   | Currently considered for risk assessment at the LOQ.   | STMR value would be assumed to be at the LOQ, unless there is scientific evidence that residues are “essentially zero”- exaggerated dose trials etc.  |
| Uncertainties           | <p>There are ‘standard’ uncertainties within the exposure assessment as well as other, non-standard uncertainties.</p> <p>1. (Standard uncertainty) The toxicological reference values are established from the thresholds derived from the dose response curves. A standard uncertainty factor of 100 is applied; an uncertainty factor of 10 to take into account the toxicological studies are undertaken on laboratory animals and an uncertainty factor of 10 to take into account variations in response that may occur for different individuals in the population. Additional uncertainty factors may be applied if the studies do not fully comply with the guidelines/guidance.</p> <p>2. (Standard uncertainty) Uncertainties relating to the representativeness of the data set e.g. small sample sizes not giving the entire range of possible residue values; the use of default factors (variability and processing factors); extrapolation</p> | <p>Uncertainties 1, 2, 4, 5, 6 and 7 listed for the HSE model would also apply to the EFSA PRIMo model. The following additional points are noted:</p> <p>Food consumption data used in the EFSA PRIMo are not fully comparable; the design of the surveys may differ significantly; the statistical analysis of the consumption data (e.g. calculation of mean or high percentile consumption) is not standardised.</p> | <p>Uncertainties 1, 2, 4, 5, 6 and 7 listed for the HSE model would also apply to the JMPR models. The following additional points are noted:</p> <p>The JMPR models rely on consumption data being provided from member countries. The design of the surveys may differ significantly; the statistical analysis of the consumption data (e.g. calculation of mean or high percentile consumption) is not standardised.</p> <p>The models also do not contain accurate information on the consumption of processed vs unprocessed foods.</p> <p>The Models use the GEMs (global environmental monitoring and assessment programme) cluster diets in which the food available per capita in a country is estimated from trade balance sheets (i.e. food produced, imported and exported). Specifically for the chronic model, only data from the GEMs Cluster diets is included. The cluster diets do not give details on which population groups are consuming the food, particularly children which are often the critical groups for exposure</p> |

|                        |   |  |
|------------------------|---|--|
| <b>Area of concern</b> | <b>Pesticides</b>   |  |
| <b>Organisation</b>    | <b>HSE</b>  | <b>JMPR</b>  |
|                        | <p>uncertainty where data for one crop/crop group are extrapolated to other crops.</p> <p>3. (Standard uncertainty) UK models are based on relatively old consumption data and may not account for changes to consumer habits, diets and typical bodyweights. Detailed consumption data aren't available for all food products, including some commonly eaten and readily available foods. It can be difficult to make meaningful refinements to the exposure assessment due to a lack of detailed consumption data, specifically considering commodities eaten following processing (i.e. consumption data for raw vs. cooked vegetables such as cauliflower or carrots).</p> <p>4. Models don't assess/account for case specific non-standard uncertainties (i.e. where there are some inadequacies in the data or where data are non-standard/not fully in accordance with the guidance such as the impact of not having robust CF/PF or resulting from measurement uncertainty, in situations where the analytical methods used for the determination of input values are not fully validated for all components in the residues definition for risk assessment). The impact of the</p> | <p>owing their high consumption relative to their body weight. As such it is not suitable for estimating children's exposure or for assessing less than lifetime dietary exposure. For info, the GEMs cluster diets relevant to EU countries are also included in the PRIMo model.</p> |

|                        |  |  |             |
|------------------------|--|--|-------------|
| <b>Area of concern</b> | <b>Pesticides</b>  |  |             |
| <b>Organisation</b>    | <b>HSE</b>   |  | <b>JMPR</b> |
|                        | <p>non-standard uncertainties on the result of a standard assessment must be judged, usually by 'expert judgement' using case-specific assessment of the available data/scenario.</p> <p>5. Doesn't account for exposure to low levels of chemical mixtures which could cause toxicological effects due to additive or synergistic interactions; the potential for interaction or toxic effects of different substances in combination is not routinely addressed by the standard single substance assessment approach. There is limited understanding of human exposure to low-levels and mixtures of chemicals. The exposure is calculated separately for each pesticide. The calculation of cumulative exposure resulting from more than one pesticide is not determined.</p> <p>6. The models are not able to account for combined exposure resulting from operator/by-stander exposure i.e. aggregated risk.</p> <p>7. Models are deterministic and as such they do not allow a prediction of the level of protection i.e. the percentage of the population that exceeds a certain exposure level defined by risk managers.</p> |  |             |

2100 <sup>1</sup> – Consideration of approaches to LOQ values (will be of significance for cumulative exposure). EFSA approaches (EFSA, 2019c) have been to use upper  
2101 (assuming LOQ) or lower bound (assuming zero).

2102

2103

|                          |  |  |  |
|--------------------------|--|--|--|
| <b>Area of concern</b>   | <b>Veterinary Medicines</b>  |  |  |
| <b>Organisation</b>      | <b>VMD</b>   | <b>JECFA</b>   |  |
| Uses                     | Assessment of potential exposure for MRL setting and review.   | Assessment of potential exposure for MRL setting and review. |  |
| Model/ Calculation tool  | Theoretical maximum daily intake (TMDI)  | EDI  | GECDE  |
| Origin of substance data | Residue depletion data in line with VICH guidance. Doses administered to animals at the highest proposed/recommended dosage regimen.           | All available residue depletion data.                        |  |
| Assumptions              | TMDI < ADI is acceptable<br><br>Chronic exposure only.<br><br>If substance also used as a pesticide, then TMDI has to be below 45% of the ADI. | EDI < ADI is acceptable<br><br>Chronic exposure only.        | GECDE < ADI is acceptable<br><br>Less than lifetime exposure should be considered for relevant populations (e.g. children or pregnant women)<br><br>When the ADI/ARfD is based on an acute exposure toxicological endpoint the GEADE is calculated |
| Consumption data         | Food basket approach   | Food basket approach   | Individual national survey from different countries (CIFOCoss, based on FoodEx2).  |

|   |   |   |   |
|---|---|---|---|
| <p>Approach</p>                         | <p>Residue levels at the MRL are multiplied by the consumption factor of each commodity, and the result is summed up to compare with the ADI.</p> <p>MRLs are usually derived using the upper tolerance limit (UTL 95/95) at the expected withdrawal period for the substance according to the proposed used.</p> | <p>Median residue concentrations associated with the MRL (at the expected withdrawal period for the substance according to the proposed used), are multiplied by the consumption factor of each commodity, and the result is summed up to compare with the ADI.</p> | <p>GECDE = Highest exposure from one animal product + Total mean exposure from all other products</p> <p>(Highest 97.5th percentile consumption plus the highest mean across surveys from different countries).</p> <p>Residue levels used are median values at the expected withdrawal period according to good veterinary practice.</p> |
| <p>Consumer groups/ critical groups</p> | <p>No consumer groups. Only adults are considered.</p>  | <p>No consumer groups. Only adults are considered.</p>  | <p>At the moment, exposure estimates for all potentially relevant subpopulations (e.g. children, general population and pregnant women [or a suitable surrogate])</p>   |
| <p>Body weights</p>                     | <p>Adult (60 kg)</p>  | <p>Adult (60 kg)</p>  | <p>Adult = 60 kg</p> <p>Children = 15 kg</p> <p>Infant = 5 kg</p>   |
| <p>Refinement</p>                       | <p>If TMDI &gt; ADI, then lower MRLs are proposed based on residue concentrations at later timepoints on the residue depletion studies.</p>   | <p>When the residue data are insufficient to calculate the EDI, the TMDI calculation is used instead.</p>   | <p>Instead of using the highest mean and the highest 97.5th percentile consumption across surveys, calculation can be made using the mean and the highest reliable percentile for each individual national survey from available datasets (CIFOCOss) from which data</p>  |

|               |  |  |  |
|---------------|--|--|--|
|               |  |  | can be obtained. The mean and the range of these estimates is compared with the ADI. |
| LOQ values    | Usually values < LOQ are considered as 1/2LOQ. | Usually values < LOQ/LOD are considered as ½ LOQ/LOD.<br><br>When there are no detectable residues in the depletion studies with radiolabelled and non-radiolabelled drug in the tissue at the timepoint on the depletion curve corresponding to the MRL recommendations, MRLs based on 2xLOQ should not be included in the calculation. | Usually values < LOQ/LOD are considered as ½ LOQ/LOD.                                |
| Uncertainties |  |  |  |
